Hi Terry , the 3.6 volt rail seems good . What does seem to be the problem is the loading (DC resistance of the AGC rail) . When the set has been running for about 1.5 hours the readings of 2.2 meg and 4.7 meg are correct . When the radio is cold the readings are 1.6 megs and 5 megs . I think this is why i was looking for a leaky component during its warm up period . 73 Alan G4MJO

It seems that perhaps W5RKL, Mike, might have the same diagnoses as you've preliminary discovered.

The 4th post down has a good synopsis within his final writings.

Subject: [TS-520_820_530_830] TS520 Transmit Issue

Hello guys, I am hoping you can help me out with the transmit issue on my 520. It was transmitting just fine until one day I was told my CW signal had a hum on it. Well everything else checks out okay as far as receive, on frequency transmit, but it has a serious (what seems to me) a 60Hz hum on it or similar. Could it be a capacitor on the drive or final section. I love using this rig for my straight key CW operations and would like to get it resolved. Please help. I posted a video on youtube to show you what is happening on the oscilloscope, and the audio is lousy I know, but maybe you can still hear it. The scope is fed with the audio from the TS440 in the video. Thank you all.

Rick and William,

It's quite possible the AC ripple (Hum) heard on the CW signal can be caused by a failing 210 or 300 supply filter capacitor. Those 2 supplies provide the B+ voltage to the driver tube and the screen voltage to the final tubes. Those capacitors are located on the left rear below the VOX and Marker boards, 2 black dual 22ufd 350VDC can caps, each one has two 22ufd 350VDC capacitors in each can. Replacement are not easy to find. They are labeled C15A/B and C16A/B on the 520 schematic.

I doubt the HV filter capacitors are the source of AC ripple (hum) on the CW transmit signal. If the 520 is still producing full output, even with AC ripple on the CW transmit signal, then the HV caps are most likely not the source of the AC ripple (hum) on the CW transmit signal. More than likely the source is either C15A/B or C16A/B caps located below the VOX and Marker unit boards on the top left rear of the 520 chassis.

A further update. As suspected the cathode resistors were open and the 470 ohm resistor alongside it had also failed. I replaced these 3 components and we have lift off! - well TX anyway with 100 watt output CW & SSB.
I have made a further clip to demo how the radio is operating.
https://www.youtube.com/edit?o=U&video_id=kWZFV5htf4w
https://www.youtube.com/edit?o=U&video_id=kWZFV5htf4w
There appears to be still a "minor" problem with IP meter reading when tuning as you will see in the clip.
As I noted in the last clip , the close up of the PA board, there had been some repair work done previously and rather large amount of solder had been used. I wonder if some tracks on the PCB are now connected by the river of solder causing the reading. You can see from my SWR/PWR meter that the RF output power is right on the mark. Should I remove some of the solder with braid to clean up the board & re solder the components? Or is there something else to consider?
The needle does move around more quickly than in the past when talking also but my signal and audio reports on the Southern Cross DX net tonight were all excellent.
The other resistors on the board measured correct values as per service manual
Thanks all for input and assistance so far.

Ken,
I use the carrier knob on the rig to adjust the carrier. The higher it is set, the higher the needle goes when releasing the PTT. I worked with the switch a bit more last night and it isn't an issue now.
I also tried out the mic last night to see if I was getting out at all. Not a peep.
I tried having just the switch and the mic element directly attached to the cable wires to completely eliminate the stand. The PTT works fine, but no transmission.
I've double checked connectivity through the pins to the switch and mic in every way I can think of and it's all connecting good.

48269. Cost and Kit info for DDS VFO

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-19 13:34:00 UTC
From: <cocobean64@...>
Topic: 48269 Message: 48269

Hello Everyone,
I've finalized the unit and totaled it all up. The majority of cost (about $200) is in the cabinet, display, encoders and two Arduinos.

Here's a breakdown of the cost.....prices included shipping to my QTH
Main Cabinet;
5" LCD Touch -$58
TFT Shield for Due -$13
Arduino Due -$40
Proto Shield -$15
2 Encoders -$50
Small Knobs -$8
Cab Feet -$10
Vfo Knob -$25
USB Panel Mnt -$8
USB Cable -$7
IDE Cable -$10
Cabinet -$60

In Radio;
Arduino Mega -$24
AD9850 -$10
RC cables -$5
Relay Module -$7
15x100 Ohm -$2
15x90 Ohm -$2
1x56 Ohm -$0.20

Misc;
Stackable Pins -$10
Jumper Kit -$6
Misc Leds -$1
Power Switch -$1
Led holder -$1
Power/data cable(s) -$6

Total is roughly $375

You could lessen the cost with a cheaper cabinet, smaller display.....
The initial response to this project was " When can we get one" or "Kits!" but after posting the cost, this died faster than "fart in a windstorm" so I will not offer or make any "kits".

Save some more $ and you can buy an IC-718 which will do the same + more, but that's not why I built this, I wanted this for more enjoyment out of my Kenwood hybrid.
If you decide to build your own version and want my code.....get a hold of me.

Larry,

I don't recall if you have tested a known-good mic on the rig. Have you?
If you have a mic that works on the rig then set your DMM/VOM on the
lowest AC scale and measure across pins 1 and 4 of the known-good mic.
Whistle into the mic to see the response on the meter. Repeat the test
with the D-104 and see if the response is similar.

You say you have a meter response when measuring directly across the D-104
mic element in the head. I do not understand how you can have a meter
response there and not get the same response when measuring across pins 1
and 4 of the mic plug UNLESS there is a wiring error OR you are measuring
across the wrong pins in the plug.

OK if you have a solid 3.6vdc RF-1 voltage at IF board Conn 8 RFG pin then most likely you have solid 3.6vdc available at R199 2.2 meg resistor that feeds the rail. Only thing that could impede that is a high resistance solder connection at Conn 8 Pin 2 and can typically see that by gently rocking the molex connector body back and forth as you monitor the AGC rail voltage.

By the way R199 may be labeled incorrectly as R149 on your schematic and silk screened as R199 on the board. There is another and correct R149 supplying Pin 6 of Q26 Processor Limiter chip. The R199 you are concerned with is physically located between Conn 8 and Conn 9 and I have never seen a bad one as very little current involved. So cant see heating of R199 being the problem.

Well as I mentioned not likely that any of the Gate 2 of the gain controlled mosfets are leaky or the meter FET gate. That leaves AGC timing capacitors as suspect. You have the bigger ones close to R199 and smaller ones at each IF amp and at Q1 RF amp. I have never replaced Q1 time constants R12 or C45. I suppose you could pull Conn 5 on RF board and eliminate that end of the AGC rail as suspect.

I think you said you disabled the AGC to make sure that Q10 wasnt involved. I suppose you could replace Q10 and Q11, but that would be guessing. Sometimes easier to just do that. If you pull the IF board to replace them I would also replace the following caps as a minimum:
1. C177 1uf (make sure installed correct polarity as some rigs it is reversed)
2. C184 .22uf
3. C83 .022 or .033uf

KW used a variety of values for C83 including .22uf, .022uf, .33uf, and .033uf. I would re-install either a .022 or a .033.

Problem is if you replace all these components and it fixes the problem you wont know what was wrong and that drives me nuts!

Lastly did you mention C60 as suspect? C60 works with the -6vdc that back biases the detector diodes to set the AGC threshold level. I would think that being leaky would affect when Q10 begins to turn on. Have to think about that some more. Could easily replace it if changing the rail timing caps.

That is the best I can do for you. Good luck.

Christopher,

You said you removed a "470 ohm 1 watt" resistor from the final amplifier PC board. There isn't a 470 ohm resistor on the final amplifier PC board.

I did not see a 470 ohm resistor on the final amplifier PC board in the video you made that shows the bottom of the final amplifier PC board. If you look at that video you will see a 1/2 watt 3.3K (ORANGE ORANGE RED) resistor next to one of the 10 ohm 1 watt cathode resistors. Is that the resistor you are referring to as "470 ohms"? I hope not because that's the meter multiplier resistor and it's 3.3K 1/2 watt not 470 ohm 1 watt.

Also, do NOT leave the transmitter keyed when the IP meter pegs fully to the right as you show in your video! The meter can be damaged.

Mike

I agree with you it appears wrong value of meter multiplier installed.

It looked like he had very high plate current in tune mode(260ma) which is not possible if half screen grid voltage and normal operating bias voltage.

Appears he had approx 260 ma in Tune and his dip was to approx 200ma. That is not possible in Tune. Should be on order of 75ma and dip to approx 60 ma.

Terry,

Yes I agree. It sure didn't look right to me when I watched the video. When he said he removed/replace the 470 ohm resistor I thought, "which 470 ohm resistor? There isn't a 470 ohm resistor on the final PC board."

If the 3.3K multiplier resistor was, in fact, changed to 470 ohms then Christopher's 60ma indication, in IP, is wrong and if he keeps the transmitter key in CW mode with the meter switch set to IP with the meter pegged fully to the right, the meter can be permanently damaged. The IP in TUNE mode should be much less. It would be interesting to see what the cathode voltage is now with the replaced resistors with 60ma of idling current showing on the IP meter. He can do that by measuring the cathode voltage, leaving the meter switch set to any position than IP.

Looking at the video link, I can see a "3.3K 1/2 watt" resistor which is the meter multiplier next to one of the 10 ohm cathode resistors. I don't know where Christopher found a 470 ohm resistor on the final PC board, it's simply is not there.

I thought about you asking him to meter the IR drop with a DMM, but I think having him validate that R4 is 3.3k and not 470 ohm is the way to go. He should not rely solely on reading and interpreting the color bands. Also make sure no less than 5% tolerance.

The TS520 meter is approx 600 ohms internal R so with a 470 multiplier almost splitting the IR drop across the 5 ohms in half. A lot of voltage to apply to a meter movement that likes to see approx 0.27vdc for full scale.

See some pretty strange work done on these rigs and maybe previous owner got confused about R5 or R6 on the HV Rect board and thought they were talking about R4 on the final board? Pretty far fetched, but why would anyone install a 470 ohm in place of a 3.3k?

Anyway just wanted you to know I agreed with your assessment not that you need any help! Just moral support!

Terry,

Yes, if the meter multiplier resistor, R4, was changed from 3.3K 1/2 watt to 470 ohms 1 watt then the IP meter indications in both TUNE and CW mode will be wrong. That is why I think the meter is pegging fully to the right in CW mode and the IP indication is way too high in TUNE mode. R4 must be 3.3K 1/2 watt not 470 ohm 1 watt.

Terry and others,

Yep and I forgot to include the voltage applied to the meter assuming 60ma of idling current flowing in the final tubes and R4 changed from 3.3K to 470 ohms.

The voltage applied to the meter will be "+.168VDC" with R4 being 470 ohms verses "+.04623VDC" with R4 being 3.3K.

The key is the voltage drop across R4 meter multiplier, which is +.131741 volts with R4 being 470 ohms verses +.25377 volts with R4 being 3.3K. The higher the voltage drop across R4 the lower the voltage will be that's applied to the meter in IP position. The opposite is true, the lower the voltage drop across R4 the higher the voltage will be applied to the meter!!!

This is why Christopher's IP meter is way too high in TUNE mode and pegging fully to the right in CW mode!!! R4 MUST be 3.3K not 470 ohms!!!

One more thing.

Assume the cathode voltage is +.3VDC (60ma idling cathode current) and the meter multiplier resistor is 470 ohm, calculate the current through the meter circuit then the voltage drop across R4. Subtract the voltage drop across R4 from the cathode voltage and you get the DC voltage that will be applied to the meter! In this case the DC voltage applied to the meter (IP setting) is 3.5 times higher than it should be, again resulting in a significant error in the IP meter indications in ALL modes!

Dave:

At least someone is reading and paying attention ! Objective was to make sure he didnt install a 20% tolerance. At no less than 5% he sure could!

Yes original was a +/- 5% tolerance. Good enough for a meter that smallest graduations is 10ma and we arent too concerned about precisely measuring 200 or 225 ma.

I like to use 1% for meter multipliers as they are cheap.

Kind of like back in the day when we built our Heathkit VOMs and VTVMs. I actually built an RCA VOM first from a home correspondence electronic course I took. It looked a lot like a Simpson 260 but then I digress.

Thanks
Terry K9TW.

Terry, Dave, Christopher, and others who are following along,

I did the calculations using a 3.3K resistor with both 5% and 10% tolerance ratings. I used +.3VDC of cathode voltage (typical with 60ma flowing in the final tubes and 5 ohms of cathode resistance). The calculations are based on the resistor being 3.3K and tolerances are 5% and 10%. I am well aware that resistors are not always what their color band state but for this discussion we will assume the resistor is 3.3K and either 5% or 10%. I also assume the meter internal resistance is 600 ohms. Not all meters will have exactly 600 ohms but, again, for this discussion we will assume the meter's resistance is 600 ohms.

R4 is 3.3K 5%:
The meter circuit current is .0000738 amps (73.8ua). The voltage applied to the meter will be approximately .044383VDC.

R4 is 3.3K 10%:
The meter circuit current is .0000709 amps (70.9ua). The voltage applied to the meter will be approximately .042633VDC.

That's a difference of 2.9ua and 1.75mv between 5% and 10% tolerance resistors. I do not believe that small difference in current and voltage will result in a change in the meter indication, in IP position, that will be of any concern.

I am not saying one should use 10% resistor for the meter multiplier.
I'm simply showing the difference between 5% and 10% resistors used in
the IP meter circuit, nothing more.

Yes. This is what I am shooting for and why i acquired both filters - CW normal at 1.8khz and 500Khz narrow and SSB 1.8khz narrow. I am planning to do it this weekend. I am glad the feedback indicates it should be relatively simple and thanks to all of you who replied. The biggest headache seem like it will just be carrying the beast downstairs to my shop.

On a separate note, as far as I can tell my TS-530 is working fine on all bands that i use (10-40, i don't use 60/80/160 so cannot comment).. As long as i have it out on the maintenance bench, is there any general maintenance that is worth doing? I am planning on cleaning some of the key contacts with deoxit and also the fan. Any other recommendations? I would like to do a check of key parameters to make sure everything is ok but not to the extent of pulling more boards, etc.. If it ain't broke, don't fix it.... but i would like to tackle anything preventative worth doing while i have the hood up.

btw, i will scan/search the forum for posts of this type to build a list of activities that seem worth doing, now or in the future, but any comments here are appreciated. for reference, I have a good quality dmm, general soldering and electronics tools, vom, vtvm, freq counter, but no o-scope.

Regards,
Al KJ3Q

Mike, Dave, Chris and others:

All I was trying to say is he had 3 choices to make when specing a replacement meter multiplier resistor. It may not have even entered his mind that he had those choices. May have simply reached for a commonly available 20% resistor that he had on hand? Of course we know that meter multiplier tolerance has absolutely no bearing on the meter pegging.

In addition to the correct ohmic value I wanted him to be aware he needs to select correct resistance tolerance and of course wattage rating. We know that if he installed a 470 ohm in lieu of a 3.3k ohm that is the reason for the pegged meter. Selecting a standard 20% resistor of course as I just mentioned has nothing to do with the pegged meter, but I still wouldnt install one in lieu of the original 5% tolerance resistor unless it meant the difference in getting on the air or not.

When it comes to metering circuits like cathode meter shunt resistors and meter multiplier resistors I would use nothing Greater than a 5% tolerance resistor as the KW design engineers speced. I have no problem going from carbon to metal film. Just would stay with original ohmic value, wattage, and resistance tolerance. Unless of course operating experience proves that the original design was flawed and we dont see much of that with KW hybrids.

Just the way I do business.

I'm also interested in this information. I believe that you can use a cable with a 1/4" phono plug and connect the sheilded cable and braided cable to the key.
I haven't found any pre-made cable for this. All of them now are for 8-pin or 10-pin.

If you mean the two pin connector on a 92 RF millivoltmeter it is an Amphenol microphone connector.

For all those following the progress and offer suggestions, a couple of further developments.
The 470 ohm resistor has now been replaced by the correct value 3.3k resistor. I think I got the 470 value from the coil on the PA board L2 470 uH, and resistor in the kit I purchased had a 470 ohm resistor. That combined with using the wrong range on the borrowed DMM to measure the same resistor on another 520s.
Anyhow, todays video clip shows the radio tuning up properly with acceptable readings (I believe) for plate & power output. I adjusted the plate idle current using the bias control to 60Ma as per manual.
I have taken measurements of the voltage of the SG Pin and the 2 x 10 ohm resistors and this also checks out at +262 volts. I didnt take a HV voltage measurement as the borrowed DMM is not rated high enough and the owner doesn't want it melted. On the front meter the HV sits about right at 900 volts.
https://www.youtube.com/watch?v=8shgMUZr5OI https://www.youtube.com/watch?v=8shgMUZr5OI
What is happening though is during the course of an extended SSB transmission, the plate current starts to creep up past the 60 Ma setting. After around 2 minutes of SSB TX with no modulation the Ma reading was creeping past 80 Ma and slowing moving upwards & upwards.
This is the initial fault I observed before the radio lost TX - I expect this is when the resistors failed first time around.
What do I need to look at , test or measure to address this?
I am reading all responses carefully and appreciate your input and kind assistance

Christopher,

The creeping up of the IP current quite possibly be caused by excessive gas in one of both of the final tubes.

I seem to recall you said you had a spare set of 6146Bs. I recommend you pull the suspected gassy 6146s and put the spare set of 6146Bs in and test. Yes you will have to check and, if necessary, neutralized the final but for testing on 40 or 20 meters, for now, you won't have to do that. You are only concerned to monitor the IP current as before to see if the IP current begins to creep up. If the spare set of 6146Bs are not gassy, I suspect the IP creeping up will stop.

I've had experience with this problem before in my HW-101. The final amplifier in the HW-101 is the same as in the KW hybrids, 6146 based Class AB1. The 6146As in the HW-101 were very gassy, sat in a garage for 20 years, and after a few minutes of transmitting, the PLATE current meter (same as IP meter in the KW hybrids), would start to creep up above the 50ma idling current and became unstable to the point that eventually pegging fully to the right and an arc occurred in the final tubes. The problem was caused by excessive gas in the final tubes. I replaced both final tubes with known good 6146As, problem solved.

I tried it out last night and immediately got a response. Got a 5-9 report from central FL, and I'm in Arkansas.
I'm very excited to get this working after hitting every stumbling block on the way.
Thanks again!!!!

Larry

Larry,

In addition to a working mic you also gained a bit of troubleshooting experience. I'll bet the NEXT mic will not take long to get going!

Congratulations, again!

Bill,

That would be up to Christopher if he wants to try that but I wouldn't recommend it.

I do not know of any extensive testing that has taken place using that method of filament power only for hours and hours to eliminate gas in low power transmitting and receiving tubes. There are plenty of hams who believe in this and will say it's a good idea but none of them have provided any factual proof from tube manufacture's that supports this, almost everything I have read is all "I do it and it works.." but how do they know it works? What further testing have they done that clearly shows this method works? If there is definitive proof from a tube manufacturer, I sure haven't seen it in the 47 years being a ham, 22 of those years was being a Radioman working in and around electronics.

Barium is used as the gas absorbing material in low power transmitting and receiving tubes. The shinny coating on the inside wall of the tube's glass envelope is the result of the "getter flash" that took place during the last phase of the tube's manufacturing. This "getter flash" occurs when the tube is vacuum pumped and sealed at the base, and the top for the top plate cap connection tubes. A high level RF generator operating in the 27Mhz and/or 40Mhz frequency range is passed over the tube. The RF generator is not held in one place but rather is moved otherwise the Barium ring, cup, or holder of the Barium would melt.

The RF generator system, when placed over the tube, acts like the primary of a transformer and the "getter element" acts as a shorted secondary. Heat is produce in the Getter element which causes the Barium to "vaporizes" (flash), absorbing any residue gas in the tube and depositing the vaporized Barium on the cool inside wall of the glass envelope, usually next to the getter element. The shinny coating continues to absorb gas but heat is require for this to occur and the filament simply cannot produce the level of heat required within the tube, 200 to 1200 degrees centigrade. Yes the filament gets very hot but that heat is not distributed evenly throughout the tube in order to heat the barium coating on the wall of the glass envelope to absorb gas. The tube has to conduct in order to produce the level of heat required and that can only occur when the tube is in operation, not sitting with only the filament glowing.

The lower power tubes such as the 6146 do not have a gas absorbing material coating the filament that some folks tend to believe. I suspect that is where the idea of running a 6146, for example, for 24 to 48 hours will absorb the gas. The only tubes I am aware of that have a gas absorbing material coating the filament is the Ceramic tubes such as the

4CX250 and other similar type tubes. The ceramic tubes have a required warm up period specified by the manufacturer (see the tube manual for each specific tube for details). This "warm up" period allows the gas absorbing filament to heat up and absorb any gas before the tube is place in operation. This warm up period is required every time the tube is being used.

Mercury Vapor Rectifier tubes such as the 866 and 3B28, are not the same. These tubes have a small amount of Mercury paced inside the tube itself during manufacturing. When the tubes are to be used, the filaments are power up for a short period of time, before HV applied. This is typically a minute or two. After the proper "warm up" period, HV is applied and the tube glow a pretty "Blue" color. The "blue" glow is the vaporized Mercury. When the tube is powered down and cools, the vaporized Mercury turns back into it's liquid state and the same "warm up" period is required the next time the tube is being used.

This is not the same for high power tubes such as the 4-400, 3-500Z, and others. Those tubes have a gas absorbing material coating the "Plate" which is typically Zirconium which also requires a high temperature to absorb gas in those tubes. The temperature range for Zirconium to absorb gas is approximately 1000 degrees centigrade. This typically occurs when the tube's plate turns a "dull red glow" during normal operation. One of the worse things an operator of a 3-500Z amplifier or other tube amps using these tubes, is to operate the amplifier without the dull red glow. Many hams I have spoken to and I mention the dull red glow, tell me they reduce drive so the plate no longer glows red. That's wrong, they should never do that.

48301. TS-820S: no power output but power burst on first PTT action

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-20 18:54:29 UTC
From: Jose V. Gavila
Topic: 48301 Message: 48301

Hi all,

I am dealing with a TS-820S with an unknown (to me) problem. It barely generates a couple watts on CW (and even less on SSB mode and none on TUNE). But there is some curious behaviour: when you press PTT on CW mode, there is a power burst around 120W (measured on peak mode with my LP-100A)

I have checked and all voltages, both on finals and friver tube are OK and keep as they should when PTT remains closed. But power then is about 2W. So I have checked from finals back to previous RF stages, and driver tube output also decreases, as does driver input. I mean, first burst (few miliseconds) is OK but then signal gets weaker.

Going backwards even more, I see that injecting a 30mV signal on RF UNIT TIF input gets about 50W output, so it seems that the problem is on IF unit, where TIF is generated.

I have cleaned and checked both relays, and they are fine.

Any hint regarding the cause of this problem?

Thanks and best regards,

JOSE

Mike,
Nice, clear description of "getting".

Way back, we were taught :
C
700 Dark red
800 Dull cherry-red
900 Cherry-red
1000 Bright cherry-red

I have no experience of high power tubes with glowing plates.

Do tube manufacturers ascociate bright cherry red or dull red with 1000C?

Dave,

I've never heard of the color verses temperatures you speak of.

For those members who would like more information about low power transmitting and receiving tube and high power transmitting tubes gettering/degassing with Barium and Zirconium, Tom, W8JI, has a website devoted to this subject (see the following link):

http://w8ji.com/vacuum_tubes_and_vaccum_tube_failures.htm

Scroll down to "Internal Anodes".

Dave In the states we would use Color charts usually in degrees F for heat treating of steel. I believe Cherry red would be in the range of 1300 to 1400 degrees F. People who practice the black smith hobby are very familiar with using color to gauge steel temperature.

If I was to determine whether a high power transmitting tube anode should show any color I would first consult the manufacturers data sheet and then consult the forums to see what the consensus is for a particular tube.

Hams who run high power amplifiers with glass envelope tubes like 3-500Z learn from experience what normal color should be. Sometimes painful and expensive experience! Of course there are degrees of color for a given color like orange and you will read about full orange for a 3-500Z and some say it must show red for any gettering to occur. Tom W8JI has some good info on his website.

Jose:

Did you try cleaning RL-1 aux relay contacts on the Relay unit board? (not the Ant TR relay). Same relays and can swap them.

Did you measure the ALC bus (rail) voltage at the IF board on Conn IF-3 on the AGL pin? Need to use a 11meg meter and should read approx 3vdc. If dirty contact on RL-1 then may have momentary ALC voltage applied to AGL terminal which would then momentarily turn on TIF amp Q1.

Yes, I have cleaned and checked it, and works fine.

> Did you measure the ALC bus (rail) voltage at the IF board on Conn IF-3

It measures, on CW and SSB, 2.8V on receive and 3.3V on transmit. Is
that OK?

Regards,

JOSE

Jose

I am sorry I did not read your post as carefully as I should have. You stated you cleaned both relays. Not sure how I missed that. Sometimes it takes multiple cleanings and swap of the relays.

For TIF output from the IF board most common problem is lack of RF-1 voltage at AGL. I would still confirm that you have approx 3 vdc at AGL.

If you do, then next most common would be no CAR level bias voltage available for the Balanced Modulator diodes. You can measure at CV pin at Conn IF-5 and also at TP-2 and vary the CAR LEVEL pot thru its range and should see 0 to 9vdc.

OK, no problem. Yes, they are clean and work the same on both positions.

> For TIF output from the IF board most common problem is lack of RF-1
> voltage at AGL. I would still confirm that you have approx 3 vdc at AGL.

Yes, it is about that (2.8V on RX and 3.3V on TX)

> If you do, then next most common would be no CAR level bias voltage
> available for the Balanced Modulator diodes. You can measure at CV pin
> at Conn IF-5 and also at TP-2 and vary the CAR LEVEL pot thru its range

We have something here!!!. On TP-2 I get only from 0 (CAR LEVEL at 0) to
0.5Vdc (CAR LEVEL at 10)

I will follow the schematics but... any further hint ;-)?

Thanks!

Yes that is OK.

After you verify you have CV voltage at TP-2 then I would measure the RF drive level at the Drain of Q18 buffer amp. This is the Double Side Band Suppressed Carrier DSBSC signal at output of the BM. It should be approx 200mv rms. Measure with O-scope or RF millivolt meter.

At the CV pin, signal goes from 0 to 9Vdc, but at TP2 it goes from 0 to
0.5Vdc. So, should the signal at TP2 go also to 9Vdc?

Regards,

JOSE

Mike: I have never heard of it taking any elevated temperature for the deposited barium on the glass envelope of a Flash gettered tube to oxidize any entrained gasses that may be leaching out of the tube over the tube operational life after that initial deposit from induction heating of the getter ring. It has always been my understanding that any time any gas leaches out of the materials it immediately reacts with the deposited barium and expends it and turns it white as the gasses are oxidized (barium oxide is formed).

None of the reading I have done say anything about need for elevated temperature to activate the barium that is deposited on the glass. It is there ready and waiting. All that was necessary for it to work at end of manufacturing process was to release it from inside the getter ring and deposit it on the cooler surface of the glass envelope which as you say is the purpose of the induction heating. The induction heating vaporizes the getter ring seal and releases the barium inside the tubular ring. At that time the released barium reacts with any gasses and water vapor not pulled out during evacuation and the remainder is left on the glass for continual reaction as new gases are released in operation or in storage. My understanding was the induction heater isnt used to heat the barium. It is used to release it from the getter tube which has either a thin metal shield or coating to contain the deposited barium or magnesium or what other exotic reactive metals used.

I believe that elevated temperatures in operation is what causes the entrained gasses in the metals and ceramic components to leach out at an accelerated manner where they can then react with the barium coating. If the tube is left on the shelf and never sees any operational temperature these gasses can very slowly leach out and will immediately react with the barium. If the pin seals go bad and there is air inleakage from the atmosphere the barium will be very quickly oxidized and the tube is ruined. No elevated temperatures involved here and the barium coating works quite nicely.

If it required high temperature for continued gettering action from the deposited barium how would you explain that barium coating turning white when air enters the envelope at room temperature?

Perhaps I am confused, but not how I understand how a flashed getter continues to function after being deposited by induction heating.

If I am correct I think this helps explain why people believe in "cooking" 6146 tubes with filaments on. It isnt to activate the barium getter material. It is to drive entrained gasses and moisture out of the tube internal materials so that they can be made available to react with the barium that is there for that purpose.

Now the question in my mind has always been does the filament alone produce enough heat to drive those adsorbed gasses out at any meaningful accelerated rate and if so how long would you have to "cook" with just filament to drive any gas out for the barium to react with? I am in the camp that typical cooking times employed with just the filament energized isnt done long enough to be meaningful.

Take a look at this You Tube video. f5m4ZOmbQ6Q

No there is a series dropping resistor of about 10k I believe in the CV lead to TP-2 so that variable 0 to 9vdc becomes approx 0 to 0.6vdc. If you are getting 0.50vdc at TP-2 that should be plenty of bias voltage to forward bias opposite pairs of diodes and get Carrier out of the BM.

You just need to use O-scope or RF millivolt meter and follow that DSBSC signal from output of Q18 to the switching diodes at input of your Crystal IF Filter, at output of the filter, Gate 1 of Q1, Drain of Q1,

Sorry I accidently hit Send!

After Drain of Q1 then look at TIF pin at Conn IF-3. May have a dirty Molex connector.

Remember TIF signal is low and will need good O-scope to measure it. No more than 250mv rms at output of Q1 and very low at input to RF board at approx 35mv rms. Also, at the input to the RF board TIF will not be clean on the O-scope. Will have harmonic content as you will see leak back from much stronger VCO signal. If your O scope has LP filter capability I would employ it for cleaner and more stable look.

Could be a bad IF Xtal Filter switching diode, but I would make sure you have 9vdc at Conn IF-2 on SSB and whatever other pins you need for the filters you have installed.

Mike,
Actually, I believe the 6146 filament (Cathode) is coated with a barium/strontium oxide that is used in the generation of free electrons from the cathode. This coating does in fact getter at room temp, but that is BAD for emission. When the tube is run "filament on" the cathode degasses so the barium flash getter can absorb this gas. That is why "filament aging" is useful for older tubes. It helps "clean up" the filament (cathode) restoring some of the lost emission due to gas poisoning of the cathode. The flash getter will getter gas from room temperature up to several hundred degrees centigrade. Note that the tube envelope is a silicate glass which can only stand about 500 °C before it will go plastic and be sucked in by the vacuum. Even in ceramic tubes temperature above 900°C will cause the getters to degas. (At 2000°C, the entire tube will be a puddle on the chassis with the exception of any tungsten parts.) The big power tubes, both glass and ceramic use thoriated tungsten filaments as the cathode. These big power tubes run the filament at about 1700°C and are processed at temperatures up to 2200°C. The getter material in these high temp tubes is a zirconium coating on the plate. These tubes are big because the glass versions still cannot get the glass envelope above about 450°C or it will be sucked into the tube.

Found it scavenging through the piles of cruft at the St. Louis "Gateway" electronics shop, while collecting some odd bits and pieces for other projects.

No, of COURSE it doesn't have the probe. But I -did- find the service manual on-line and there is a schematic of not only the meter, but the probe as well. I think I might even have the parts, or most of them, on hand, for the stock probe. (The 1000:1 divider I will have a job of work to get the bits for that, I suspect..... I'll certainly see, once I get into the manual a bit.)

And it even -works!! (As best I can tell!)

On the middle (NOT lower - didn't want to chance damaging it) ranges, I can make the needle deflect full scale by touching a meter probe gently inserted in the center conductor of the UHF (SO-239) connector and then touching the exposed probe tip. It came with a SO-239 to BNC adapter, but the probe is unfortunately not even for sale separately. (And believe me, I looked through ALL of his boxes of probes, and a spaghetti maze it was!)

It was sheer serendipity that I noticed it sitting on a shelf, as the store is expanding and the area where the surplus and junk equipment is stored is not even open to the public. Nobody was allowed back there, but I'm nosy and so I stuck my head around a partition anyway.

The owner was back there working on some shelving. I asked if he by any chance had a swept RF gennie in there somewhere ("No."), and just happened to spot this HP box sitting on a shelf not three meters in front of me. The store owner is an old friend/acquaintance (he recognizes me as a recurrent nightmare anyway), and so he was willing to haul it over so I could have a look at it.

I tried NOT to let him know that it was something of a real find, and must have been successful. To a tossed out, "How much?" he just said, "Twenty bucks." To an additional, "How much if it's not working?" he replied, "Twenty bucks, just like in town." and that dates BOTH of us as Aulde Phartes since I got the joke reference.

On closer inspection once I got it out into the light, there was a 1995 HP Calibrations Laboratory sticker, very faded, stuck on the bottom of this little beast.

So, now, here it sits on my bench, admittedly sans probe, but I have found and downloaded that service manual, and will be making a probe as soon as I might. I even hear there are silicon replacements for the vacuum tube diode that can be simply inserted into the tube socket to

eliminate one of the tubes, and I will be looking into that
modification. It all remains to be seen, and I'm looking forward to it.

Terry,

My info comes from a heat-tratment background. These days it looks subjective in light of the available instrumentation.

My grandfather was involved with hardening steel and used a long splinter of wood to test temperature. The rate of sparking when drawn across the hot steel - along with the degree of steel redness - provided an indication of temperature. Don't try this at home!

I digress. Mike and Terry, thanks for the link.

Hello Terry,

Thanks a lot for your detailed info. I have been following the signals as you suggested, being Q18 signal OK, and I was measuring around Q1 when a new problem has arised... The audio amplifier is self-oscillating at about 100kHz.

When I got the unit on the bench yesterday, there was a motorboating effect on audio. I resoldered the AF board, specially on the audio amp area and it went. But this morning, that effect is back. I have checked all the capacitors, replaced electrolytics, and checked all other passives around the AF amp, and they are OK. Also, pressing laterally over the audio PA heatsink, the amp starts working fine in some positions. I would say there is an internal problem on the TA7201P, as soldering is perfect and it keeps failing that way. So I will source a replacement for it and, by now, stop troubleshooting TX, as when it self-oscillates, there is some effect on 12V rail which affects other circuits even on TX.

I will be back as soon as I get a replacement.

Thanks and best regards,

JOSE

Dave

I have a little background growing up in old Fossil power plants where there were real craftsmen and all kinds of heat treating, stress relieving, tempering, annealing was performed frequently. I learned how to pour babbitt bearings and blue and scrape them and lots of things that today would be considered lost art. I eventually ran the Electrical repair shop and we did all the induction stress relieving for the Welders.

Been many years since I thought about colors. Back then we had no infra-red pyrometers or even a contact pyrometer. Temp paint sticks didnt exist. When stress relieving we would make thermocouples and read the millivolt voltage and look up temp in conversion charts. Had to use ice baths for a reference. Very primitive by todays technology.

Bill Thanks for sharing this with us. I was hoping tube engineers and chemistry majors would come out of the woodwork!

Just dont want folks to confuse flashed getter with oxide coated cathode and the function of each. Even though they both have barium in common.

I had forgot about the use of "emission paste" (I think barium and strontium carbonate?) to coat the cathodes. I understand the need to improve electron emission.

Been long time since read about activating or aging the of the cathode. There is also need to rid the adjacent support elements near the cathode of residual gasses as well. I guess this aspect isnt technically really part of activation, but goes hand in hand. We dont want these gasses to poison the cathode.

A question: During activation or aging process after pump down are these barium oxide/carbonate compounds actually converted to pure barium? I assume that is what is going on?

Very interesting subject and sure wish we had a You Tube video showing and explaining the manufacturing of a 6146B tube. I have tried to find manufacturing info for the 6146 and have only come up with operational data sheets and very little on the actual design and manufacturing process.

Thanks

Bill:

One more thing that bemuses me. No mystifies me! Maybe you can explain.

If the barium coating on the envelope remains active for many years and is active at room temperature, Why can a supposed spare NOS 6146 tube that has set on the shelf for 30 years arc over when placed in service? If the tube is sitting there off gassing why wouldnt the barium react with the gasses as they are being released thus no gas in the envelope to ionize and support an arc on initial power on.

I guess another possible source of an arc would be conductive foreign material in the envelope like a metal wisker or wire tail in the gap between elements. I hear this may be one of the problems with Chinese 6146 tubes but no direct knowledge of that.

When I watch old vacuum tube manufacturing videos I see "white glove" assembly areas so I would think foreign material entry would be rare? Even if foreign material is a possible cause for an arc over is it likely would have more than one event per tube from this cause?

I have had more than one experience with 6146 arc over events and from dc Hi-pot testing I know they have different hold off levels. Some as low as 1000vdc and will arc over. So while I agree that barium is very reactive at room temperature I do not understand how there can be any gas resident in the tube unless the barium has reached end of its useful life after 30 plus years?

I have a TS-830 that works great, 100 watts on all bands, Super receiver. Love the radio. Need some help. I can't get an IP readiing when in the TUNE position.
I can read ALC, RF COMP AND HV, BUT NOT IP. In the CW position, I can read ALC, RF, COMP, HV AND INCLUDING IP. I can't see anything out of place, unless the Mode multi switch is defective and upon inspection is operational. I can get excellent plate current dips when at resonance.

Any help is appreciated.
Enjoy the hobby as I do and the operators.

No IP in tune sounds like one of the volatage divider resistors going to the tune switch contacts or screen voltage supply are bad. Check resistor values in this circuit. Measure screen pins voltage on final tube sockets when in CW and Tune positions in transmit mode. (BE CAREFUL,)

Terry
I just observed the internal color of the gettered area of a 60y old tube - silver , broke open the stem then looked for color change at room temperature.

The silvered area reduced by half and is sill reducing! The color became black.(not white)

I conclude that the 'silver' film remains active, quietly doing it's job over a lifetime.

As I'm typing, the 'silver' has vanished!

While tube theory is being discussed, why would tubes become gassy? Mike thought this was a possible cause to my plate current creeping upwards. The radio has been used for some hours most weeks of the last year so can't imagine why they might be gassy. The radio has not been dormant! I will do a swap out to the spares which are s2001s, but I have no history or age to the spares, they came with the radio. I'll continue to do all these tests, measurements and suggestions as it's building my personal knowledge and one day I might be able to pass on some help to a younger operator.
If the tube swap test doesn't change what's happening, what next to check? It's got to be power output, tx side of the radio so that narrows it down

Terry,

When a tube sets on the shelf for long periods of time (years), the tube gases up. Getters are not 100% efficient and the efficiency varies with the type of gas. One of the worst gases is water vapor. It sticks to everything and is VERY difficult to pump out. Glass and metal are pervious to gases, especially hydrogen and helium. This gas sticks to the cold internal surfaces of the tubes envelope and internal components. This gas sticks to the first cold surface it hits These gas atoms and molecules do not simply float around -- they stick to surfaces. It sticks to the barium in the porous cathode coating. If we have a vacuum gage attached to the tube, we would see a good vacuum. But when the tube it lit, there is a tremendous burst of gas and if the HV is present--instant ARC!! When an old NOS tube is put into service, it should be filament aged for an hour or more to allow all tube components to heat up and degas so the getter can clean it up.

Mike,

This is common problem...so you are not alone. The MOST likely cause is resistors 15 & 16 on the rectifier board are way out of value. They reduce voltage to final amplifier tubes when mode switch is in the "tune" position...thus helping prevent the tubes from getting full voltage when in an out of tune state....that's bad for the final amp tubes. They are difficult to check properly in circuit. Suggest that you obtain suitable replacements....same value and wattage...metal film...is a good replacement....remove said resistors...and check value...bet they are way out of value.
You can go to the home page of this group and search for "no Ip in tune." you will get maybe 500 or so results. Lots of Kw hybrids suffer from this problem...it just a bit different resistor identification that's different

Dave:

Very interesting. Some might gasp at the sacrifice of a 60 year old tube for a science experiment!

I wonder if the getter in this vintage tube is some other volatile earth alkaline element than Barium or combination of reactive materials. Perhaps magnesium. Hard to say what they used back then. Might account for the turning black as opposed to white when acting on air ingress?

I am still struggling in my mind if the flashed getter coating is volatile at room temperature, how can an old tube be gassy in service or after being in storage for many years. Why wouldnt the getter continually and immediately adsorb this gas as it is formed in the envelope either from leaching out of the metals and insulating materials or from slow ingress around the pins and glass seals. How can any gas accumulate if active getter coating remains?

The reason I believe the tubes are gassy is I have used NOS 6146 finals that arced over shortly after energizing them. I also have seen gassy tubes affect control grid bias. That would seem to indicate the flash getter has been expended and is not adsorbing these gasses. I am assuming the 6146 arc over was from gas and not from foreign material such as a wire "whisker" in the gap. I have to assume RCA, GE and others used "white glove" assembly procedures?

I think we will never completely understand the real science here and will always be folks on both sides of this "Cooking" debate. In my mind you would have to Cook for a very long time to drive any significant amount of entrained gasses out of the metals and insulating materials where the barium flash coating could act upon them. However, I have had some 6146 tubes that will not hold off 1000vdc dc hi-pot applied between the anode and cathode and after Cooking with filament voltage only will see some decent increase in the withstand voltage. Not always but quite often. I do not understand why this occurs. Unless as the getter material ages elevated envelope temperatures do make it more reactive?

While this is very interesting subject I think I am going to move on now. My answer regards to Cook or not Cook a 6146 tube can be seen in the arc over protection mods I have installed in my radios. One thing it would seem Cooking cant hurt other than expending some emission life.

Thanks for sharing.

Bill:

Never heard or read about the off gassing clinging to the metals and insulators from where it emerges.

I had assumed the gasses just came out of "suspension" and were dispersed through out the envelope where the barium could react with it. Never thought of gasses clinging to surfaces. Water vapor leaching out makes more sense to cling or coat a surface.

So heat then may well help disperse gas where flash getter coating can act on it. That helps explain why gas can accumulate and not get adsorbed by the flash getter that we do know remains active as we have seen when mass amount of air is emitted into the envelope in a short amount of time essentially pressurizing a space that was a vacuum.

So this clinging gas could be in the path of electrons and be impacted and form positive ions and cause problems we see with tube bias.

Wouldnt it be interesting to watch the surface of an tube element under electron microscope and see this molecule of gas emerge from the metal surface and see what it does. I guess I thought with a 10 to the minus 10 atmosphere tugging on it I would have thought it would have breached the surface and rocketed off into the ether to be devoured by the hungry barium coating!

Very interesting.

Will

Not to burst your bubble and I could be wrong but dont think this is going to be much help servicing your KW hybrids. This is a DC microvolt and microamp meter. It will read very low dc uv and ua levels. It is not for measuring RF drive levels.

Some applications in your hybrid would be to measure the grid current in the FG line on positive peak of the rf drive envelope (approx 45 ua max). That is more of an academic exercise and can do it with a good DMM by just measuring the IR drop across 10k series resistor in the ALC circuit.

Could measure actual ua current flowing in your panel meter.

Could also use it as a milli-ohm meter with external battery to measure relay contact resistance.

Could be used in pipe line work to measure cathodic protection. Maybe to test your station grounds?

As I say I may be mistaken and would have to look at the manual. I believe it has a sychronous motor and lamp bulbs that work as a chopper that feeds a differential amp so combination of tube circuitry and some mechanical components.

Might post on the Yahoo HP reflector and ask who has one and how do they use it for electronic service work. Price was certainly right and will be fun to get it working.

I have a Simpson 2795 that has dc uv and ua ranges. Lowest range is 1uv and 1ua full scale! Dont use it often but nice to have if needed. I have lifted the FG lead and placed it in series and looked at 6146 grid current at full ALC deflection, but found measuring IR drop across the 10k resistor with DMM at about 0.40vdc is much easier. 0.40/10,000= 0.000040 or 40ua.

Terry K9TW.

Terry,

THIS would be your first clue (says the forensics classes I took for my Master's in Information Security) as to how the list was breached and Monsieur Sylvester managed to get back in here.

Which, by the way kiddies, is a FELONY in the United States, using someone else's accounts without their permission or knowledge. (The Yahoo people might like to know about his shenanigans and re-entry here, despite being once removed.)

Same goes for stealing internet from your neighbours, by the way. (Even if they are too stupid to put a bleedin' password and encryption on their piece-of-junk wireless router.)

Terry:
Sorry for the long delay. Spent a week in AZ and then another week catching up at work.
Took some measurements today on the TS-820 with the VTVM and VOM.

I assume you meant pin 3 on RF-3, not RF-1. Pin 3 measures 1.7 v on the VOM
Pin 6 on RF-3 measures 0.7 on the VOM as did Pin 6 on IF-3.
Measured MD-1 with the VTVM and saw about 1.0 v, but I really can't vouch for the accuracy of the VTVM. I borrowed it and should probably see about running through the calibration.

Well Tim I have slept since then! So not exactly sure where we left off.

I think I was wanting you to measure the RF-1 reference or dc control voltage at the RF board to make sure it was at approx 3.3 vdc and not slowly drifting down under key down or changing after the warm up period. If RF-1 voltage is drifting down then ALC bus voltage will drift down and RF drive from TIF amp will drift down. Very seldom have a problem with RF-1 drifting. If it does need to monitor 9vdc regulated to make sure it isnt drifting down. If 9vdc regulated is solid and RF-1 is drifting I would clean its voltage adjust trim pot VR-1 on the AF-AVR board and reset to approx 3.3vdc. .

Maybe I confused you and made you think that RF-1 is a molex connector? It is a key dc control voltage that feeds the AGC and ALC busses. RF-1 supplies the ALC bus thru a 2.2meg resistor making it a high Z power supply. As I said it is derived from the 9vdc regulated on the AVR board. It should be approx 3.3vdc and can be measured with a either a VOM or VTVM or DMM. Does not have to be a high Z meter. However, must use a high Z meter to measure either AGC or ALC bus.

If RF-1 reference or control voltage is good at RF-3 connector Pin 4 then move on to the ALC bus voltage which leaves on RF-3 connector Pin 6. You cannot measure it with a VOM as it is a very high Z power supply by design and a VOM will pull it down significantly. Even a 11meg VTVM will pull down the 3.3vdc to around 2.6vdc.

If you have approx 2.6vdc ALC bus voltage (as measured by a 11meg meter) leaving RF-3 connector then I wanted you to see if the IF board was seeing this same ALC bus voltage. It arrives there from the RL-1 aux relay contacts on the AGL line. So wanted you to measure AGL at IF board on Conn IF-3 at Pin 6. Should see the same approx 2.6vdc that you had at ALC bus leaving the RF board. If AGL is powered then your Meter FET Q4 should see it and TIF amp Q1 should see it and should get good RF drive from the IF board to the RF board.

I am not sure about MD-1? If you mean you are trying to measure the RF drive at MD on RF board you need to use a RF probe and VTVM and not just a VTVM. Should see approx 2rms rf volts of drive at output of the TX Mixer. Are you trying to watch MD and see if the RF drive voltage slowly falls off under key down?

You should look at the schematic and see if I am calling out the correct molex connectors and associated pins.Helps you learn and keeps me honest.

Also, at the input to the RF board TIF will not be clean on the O-scope. Will have harmonic content as you will see leak back from much stronger VCO signal. If your O scope has LP filter capability I would employ it for cleaner and more stable look.

48340. DDS VFO update

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-23 02:35:01 UTC
From: <cocobean64@...>
Topic: 48340 Message: 48340

Posted a couple of new pics in the album section... Added Rx Tx indicator, changed background color / button color for better viewing contrast, cleaned up the text.

7' screen is coming on Monday, will be adding "mem" buttons and a small external usb keypad for direct entry of a frequency. Should be enough real estate on the display to include perhaps a power/swr readout (bar-graph?).
I've got an extra WaveNode module, so i'll give that a try.
Since the first build has proven itself on the 530, this one is going on the 830.

Tim:

I think I need to restate the problem statement and have you confirm if I understand the problem.

1. When you load the rig from a cold power on in Tune mode you can get good ALC indication with the Car Level pot advanced and the Drive control peaked.

2. You also can then go on to load rig to normal RF output power as indicated on either the RF relative power position of the rigs panel meter or on an external wattmeter.

3. After the rig warms up RF output power drops to zero or drops to some lower level (lower than approx 100 watts output) and when you attempt in Tune mode to reload there is no ALC indication on any band. If the RF output power drops to zero you should be able to get ALC indication. If you are trying to look at ALC indication with 200ma of plate current indicated my first question would be where in the manual does it tell you to do that? Secondly, it is normal that you may have no ALC indication with decent amount of plate current. You should however be able to see ALC peaks in SSB mode when modulating the rig. Just may not see any if key down in CW mode at 200ma. This has to do with RF negative feedback that is employed and too many keystrokes to explain here.

4. Last year you installed "new" Driver tube and final tubes.

IS MY UNDERSTANDING CORRECT? If not, please clarify or amplify.

Have you tried a 2nd "new" Driver tube since you had this problem? Typically rf drive and rf output does not just instantly occur on all bands if Driver tube is getting weak. Normally it manifests the problem on higher bands first.

Lastly, if you only have a VOM or VTVM it will be very difficult to troubleshoot loss of ALC indication, loss of RF drive, and loss of RF output power. These can be different problems or related problems. At minimum you need a VTVM and RF probe(s). Easiest way to troubleshoot this kind of problem is to run TX level diagram to find where you are losing the RF drive and then focus troubleshooting efforts at that stage. You need to confirm that you have the required goes in and goes out signals and proper Dc voltages..

Absent test gear all you can do is visual inspections, tube swaps, molex connector wiggling and removal and cleaning, relay contact cleaning. pressing on Driver tube to see if bad solder connection at the socket, tapping on boards etc. Sometimes you get lucky.

If you can confirm that you have good RF-1 voltage and good ALC bus voltage that is not going way as rig warms up and still losing RF drive then you will need an O-scope or VTVM and RF probes for me to be able to help you any further.

You can use your VOM or VTVM to take all the DC voltages at the Driver tube socket and the 6146 final tube sockets to make sure operating bias is good, screen grid voltage is good. Just have to be careful taking these voltages. As stated above I normally first check for proper rf drive voltage and when I find where it is low or missing then I take DC voltages

at that stage. Usually very easy to isolate to the problem stage.

If you are going to plan on maintaining your own TS820 and being able to troubleshoot low or missing RF drive and RF output problems you will need to buy a VTVM and RF Probes or make the required probes. Very first piece of test gear that you should purchase. to work on KW hybrids. Can use DMM but VTVM is better choice.

Hi Terry, I have as yet not resolved the problem . Having replaced Q2 Q3 Q4 IF board and Q1 on the R.F board ,the receiver seems to have a reasonable amount of gain . one observation is though that with themarker on 14.75 you cannot achieve S9 I am starting to suspect reversing plugs 8&9 on the I.F board has also taken out Q2 Q3 Q4 ON THE R.F board . These devices are 2SK125 , not available in the UK , so i have had to order from china , I will have to wait four weeks for parts to arrive . On a different subject do you know where you can get touch up paint for the TS-830 front pannel . 73 Alan G4MJO

Alan;

I thought your issue was low AGC bus rail on cold turn on? I cant remember.

I think you mean you dont have S9 Marker at 14.175 and not 14.750 mhz? What Marker level do you have? If it is close to S9 with 50uv off air signal then it means the RF/IF gain controlled stages are working and the meter has been calibrated.

Only way to ensure accurate S-9 indication is to perform a good RF and IF alignment and then inject 50uv or -73dBm in to the SO-239 from your RF sig gen and then adjust the AGC meter span pot for S9.

Those without good RF sig gen with calibrated step attenuator can just perform a good coil pack alignment and then set the span pot for S9 and call it close enough for what an S-meter is best for anyway (on air comparison reports). Actually if you have functional Marker and do a good coil pack alignment this method of S-meter "calibration" works reasonably well.

If Q2 buffer amp and Q3/Q4 RIF mixer devices on the RF board are bad you would have no receiver signals at all as you would have no RIF signal leaving the RF board and applied to the IF board. These devices are not gain controlled by the AGC bus rail. Low AGC bus control voltage does not effect these two stages other than providing lower input signal from the output of Q1 RF amp.

Check with Mark Gilger WB0IQK to see if he still sells the matching paint.

Terry

48346. ts530s Driver tube volts, alc pegging, high idle plate current

Topic: 48346 Message: 48346

Where to start? new hv caps,rk-53 resistor kit , screen and driver caps, rl-1 all from k4eaa ken. Replaced q-31 on af board no voltage on alc socket 9 pin 1. Cleaned ant relay, selector switches etc.
Voltages Rx Tx usb, meter lp, mic gain 0, rf gain max, drive max, load 0, plate 14, band 14, heater on, everything else off.
final unit:
control grid bias -107 -55
screen grid 255 243
heater 12.7
drive input 0 -3
lp meter 0 0

rectifier unit:
800 b+ 754 713
hv to meter 36 33
300b+ 336 320
210b+ 257 246
210a 255 243
-c common b- -115 -105
12 screen grid cut off -114 -104
sg2 255 243
tun 128 122
14a 18 18

tubes 6146 v1 pin 1,4,6 0 1.4 pin 2 12.6 ac, pin 3 256 243, pin 5 -107 -55
v2 pin 1,4,6, 0 1.4 pin 2 6.3 ac, pin 3 256 243, pin 5
-107 -55

12by7a pin 1 0 0, pin 2 -47 +0.3 pin 3-6 0 pin 7 335 334, pin 8 207
199, pin 9 0
bias pot -107 to -95 rx -55 to -25 tx and is smooth
c
before parts replacement- 60ma idle current, no alc, no s meter, no rf, hv 750 0 watts ext meter.
post parts replacement- lp bias pot ccw 260ma cw pegs meter, alc pegs meter, rf o bounces 3/4 scale on return to rx usb and cw, hv 750, and now have s meter, still 0 watts on ex meter. Where do we go from here? working on getting a rf meter have access to o-scope. Had rf probe for dvm not real accurate but I could see rf to socket 6 pin 1 on if board but not sure of readings. any help would be greatly appreciated.

Thanks,
Ira Parker

Terry:
To confirm, I was able to tune and get power out from a cold start, but the longer the rig stayed on, plate current and ALC became erratic and I eventually lose output power. When I talk about ALC, I'm talking about tune mode when I would try to retune. Where I would initally be able to peak the ALC with the drive control while tuning, after things start going to pot I'm no longer able to see ALC while trying to retune in tune mode.

Tonight I took the driver tube out of my Tempo 2020 (which works fine) and put it in the 820 to see what would happen. Got anywhere from approximately 50 to 100 watts output measured by external meter to a dummy load. But again plate current was erratic, swinging between 110 to 240 mA, thus the flucuations in power. Keyed down a few times to see if this continued and then the fuse in the back blew and I was done. First time that has happened ever. No 6 amp fuses here so I'll need to pick some up.

Lacking the VTVM and RF probes when I put the new Taylor 6146Bs in last year, I did a poor man's neutralization by monitoring the signal level on another receiver in the shack and adjusting for minimum received signal on that receiver (SW switch off). There wasn't much change while adjusting but I did the best I could.

I think I remember seeing some plans on the internet for building an RF probe. I'll have to go find that again and see if I have what's needed.

As always, I appreciate your help and time in responding.

48349. KENWOOD NET UPDATE (March 23, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-23 23:56:39 UTC
From: Mark Gilger
Topic: 48349 Message: 48349

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday 40 meter net had 20 stations checking in under good band conditions. There were 7 new stations checking in, W3GLH, WD4AYS, KD8HLV, KD3SK, N9OTR, KB3MLT, and K2QMU. We had the following number of radios checking in.

2 running TS-520(x)
4 running TS-530(x)
4 running TS-820(x)
2 running TS-830S

I was running my TS-830s with an L4B amplifier.

The Sunday 20 meter net we had 10 check-in under poor band conditions. We had the following number of radios.

3 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
3 running TS-830S

I was running my TS-940s with an L4B amplifier.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can

alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 70, Sunday☐s total = 62 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:

OK I am a bit nervous about the Taylor 6146 tubes. If I am not mistaken those are Chinese manufacturer and I have not heard anything good about them. I have no personal experience with them and never had a customers rig with them installed. Do you have another set of finals you can try?

Typically for ALC indication to be varying like that means one of two things. RF drive to the 6146 control grids is varying and/or -dc operating dc bias voltage is varying. Unusual for the RF drive to vary. More common for it to be low or missing and not coming and going. You could measure the key down bias and it should be steady at approx -55 to -60vdc.

Can you adjust the zero signal resting plate currrent in SSB mode to 60ma and it is stable?

Nothing wrong with neutralizing using another receiver to listen for the null. You can get pretty close using that method. I dont think neutralization is your problem. When tubes take off the plate current usually pegs and doesnt swing back and forth as you are seeing.

Terry K9TW

Topic: 47979 Message: 48351

In the latest tests I have conducted, per Mike's suggestion, I swapped out the 6146Bs with a spare pair of S2001a (condition unknown). After tuning up I noted power out was considerably lower than the other tubes - 60 - 70 watts. But the point of the test was to observe plate current for creeping upwards in SSB. I adjusted the bias so it was right on the 60 mA position and left the radio in SSB transmit - no audio output. There was minimal change in plate current - perhaps moving to 70 mA but no further. I left radio in transmit for what would be a typical transmission length 2-5 minutes and the plate current sat steadily at about 70 mA.
I then swapped the 6146Bs back in to do the same test. After tuning up, mA had moved from 60 at commencement to 100 mA in 90 seconds in SSB transmit - no audio so definitely a problem with one or both of the 6146Bs.
To further test I pulled the S2001's from my 2nd 520 to do the same test. This pair were right about the 100w out and also sat steady at 60-70 mA during the transmission test.

I don't know if one or both of the 6146bs has a problem. Do I check with a 2001a and one 6146b at a time to determine if one of the 6146bs could still be OK?
I do have 1 spare 6146b also but condition is unknown.
If I change to the "spare" S2001, I will need to neutralise these - could this be a factor in the lower output power these displayed? These tubes might have just kept as spares because the output power was down.
If need be I just buy another pair of 6146 tubes ?
It appears, I'm most of the way to getting this radio back operating thanks to your help, knowledge and input.
Then there's the other 520S to start on!

I forgot to ,mention that Ken K4EAA sells the proper fuses.

Take a look at the HV filter caps to see if anything has expelled from the rupture vents and look at the HV doubler diodes D1, D2, D3, and D4 to see if any visible signs of damage.

If fuse does not blow at power on then place meter in HV and key rig and make sure you have 900vdc.

48353. Antenna relay replacement/upgrade for TS530

Yahoo group: TS-520_820_530_830 (2014)

From: Jan Servaites
Topic: 48353 Message: 48353

Anyone have a solution for a replacement for the cheap, solder-in antenna relay in the 530?
I'm looking at the Omron MY2DC12(s) and socket, Newark has them for under $6 each.
That seems like the way to go
http://www.newark.com/omron-industrial-automation/my2-dc12-s/power-relay-dpdt-12vdc-10a-plug/dp/36K3444

My repairs are progressing on receiving a completely dead 530:
1) TX - I have good ALC & RF power output (after re-alignment) on 1.8 only, but every other band is way, way down. Looks like an RF board rebuild.
2) Antenna relay - Its completely shot, even after cleaning. Jumpered the relay just to test TX output.
3) RX - Some bands are close to good (after re-alignment), some bad. Points to the RF board again.

Repairs so far:
1) Re-cap on HV & screen & all new tubes (tubes were all junk), resistor kit/plate choke cap kit installed (Anode dc blocking cap was split open)
2) AVR board replaced; All voltage regulators were bad
3) PLL board replaced; Did work originally, then went bad, but recent troubleshooting brought some systems working again.
Lots of cleaning done too

I find people ruin the Fujitsu FBR relay trying to clean the contacts in place. They bend them and break off the small plastic snubbers. I have had good luck buying pulls from Bob Mansker and carefully cleaning and adjusting and measuring the contacts before installing assuming it is the clear cased version. There is a sealed black case version that you cannot open to clean. If you buy from Bob make sure he sends you the clear case one. In my experience he will send it to you mounted on the PC board.

The MY2 is pretty big relay. Bigger than the MX2P used in the TS830. I doubt the socket would fit in the punched hole in the chassis? Might have to use nibbler and open it up some? Cheap enough to buy one set and see if you can make it work.

Ken K4EAA is just starting to evaluate the feasibility of replacing this relay with the same style that he made to replace the Omron LZN4 RL-1 relay and he is now selling on his website. They are beautiful. I have no idea if he will follow thru or when the FBR replacement would be available. I can tell you that when he sets his mind to do something he makes it happen pretty quickly and it is first class.

There is one other possibility that you could switch the transmit/receive lead wires to the opposite set of contacts. The contact config as wired sees approx 1.4 rf amps for the NO contact. The NC contacts normally see only uv level off air signals unless exposed to ESD or accidental transmit RF.

The other set of NO and NC contacts supply the Remote socket and may have never been used or just used to key a linear amp relay with DC current in the low MA range.

Terry,
Well, there's another option to use a 830 relay & socket, and maybe Bob might have some spares as well? I just don't like the 530's soldered in relay idea, and yes, someone bent the top arm and I tried to straighten it. I might check that 100pf cap that's on the relay too for shorts.

Yes the TS830 socket will fit the punched hole in 530 pa cage, but still have the problem that the Omron MX2P is obsolete. Of course can find MX2P pulls and much easier to clean contacts and re-install them.

Also, you can use a commonly available Guardian A410 series relay as a sub for the Omron, but it is about 1 mm taller and a tight fit into the shield can. Also have to remove the polarity post and install a metric screw in its place.

I have installed the Guardians in couple of customer TS830s and so far so good. I provided this info to Bill Adams WD8OSJ and I believe he is using the Guardian now in his TS830?

Jan,

Some months back I chased the FBR relay and found a company in your neck of the woods, (Stateside that is). As there were no takers I didnt continue on that journey. The price I received was $US 19.95 ea + postage and handling for the clear top relay, which then made the price jump too high. The stupid thing when I asked for the specs he send me a flyer which showed the price as under $US2.00 each, but was still asking the higher price. I was given a written guarantee that they were brand new un-used, but had a 4 day deliver wait before shipping, so obviously they didn't have them in stock. Contact me off list if you want the details.

You can get by without the relay if you just jumper it across. All it does is detect pulses from the CB pickup or ECU and run the injection pump - the idea is it will stop pumping if the engine stops for any reason. It has absolutely sod all to do with the rail pressure, that's taken care of by the little mechanical regulator capsule on the outlet side just over the hydraulic pump.

I'd rather link it out and drive home, than sit for hours in a snowstorm waiting for a breakdown truck...

The TS520 just needs a Xtal for each of the 4 frequency sockets if you want fixed frequencies,
They Have specs of the Xtal load capacatance in the manual. they just have to be within the VFO range to work..

There are empty component spaces on the RF board that names it as "AUX".
I would think some caps & RF cans (L101, L102, L103) could be soldered
in. I guess the PLL would need some programing too.

There is a huge difference between Fixed and Aux operation!

Bill isnt interested in Fixed frequency operation.

I have never seen any KW documentation that describes how to spec the tuned circuits to utilize the Aux feature on the TS530/830 rigs. If it exists from KW I would be very interested in seeing it. Of course also have to find a source of cans of proper size. Suppose could harvest coil pack cans off a parts RF board and rewind them to provide the inductance range you need. Caps to resonate the coils would be no problem.

The only so called KW service bulletin info I have ever seen on utilizing the AUX bandswitch position is for the TS820 and it was pretty useless as it basically says to install the Front End caps and coils as needed for the band of interest, install the new VCO oscillator caps and coils as needed for the band of interests, and to install jumpers on the PD unit for the band range of interest. Very helpful stuff!

Hopefully one of our members has done this to allow listening to favorite short wave station and can direct you to how they speced the tuned circuits.

Understanding the mixing scheme we could probably calculate the required capacitance and inductance values. Might start with something simple like copying 15 mhz WWV? Or perhaps copying 17.660 mhz (2nd harmonic of 8.830) so could use the receiver to adjust KW TX Mixers for lowest spurious output (poor mans spectrum analyzer).

Not sure why KW provided this feature as it is very limited way to get general coverage receiver.

What is your question?

Depending on the rev of the documentation that you have there are numerous errors on the TS830 and other hybrid schematics. Also depending on the rev of a particular pc board you have there will be component changes and as-built config that does not match the schematic.

Are you troubleshooting a VOX issue? Q13 is used to control VOX delay by discharging C49.

Bill:

We know that you will want the Q3/Q4 RIF Mixer to produce 8.830 mhz output. It does that on any of the bands by mixing the RF from the ANT and MIXER stage with the VCO which serves as the LO for the RIF Mixer. The PLL produces the required different VCO frequencies by switching in the proper band related VCO Oscillator Q1 thru Q6.

8.830mhz is the difference frequency. So using 15 mhz as the short wave band you want to listen to we can calculate the required LO. 8.830 + 15.0 = 23.830 mhz. So we put 15.0 mhz parallel resonant circuits at the Ant and Mixer vacant positions. We can calculate them and important to get the LC ratio correct which we can measure from the others. Then we need a 23.830mhz output from the VCO board. 23.830 - 15.0 = 8.830 RIF from RF board to the IF chain.

We need to have proper VCO oscillator switched in at the AUX bandswitch position. If you look at the bandswitch diode matrix it appears to me that VCO FET oscillator Q5 is used for 28mhz and for AUX positions of the bandswitch. This looks strange to me. I dont see how we can have both if that is the case. For 28mhz LO the VCO frequency is 36.83 mhz to 37.33mhz. Would require significantly different tank components to get 23.830mhz from Q5 oscillator.

When you look at Q5 will see it is a FET based colpitts oscillator that the tank resonant frequency is varactor diode tuned. Looks like T5, C31, and C33 would have to be changed to produce the 23.830 mhz VCO output to provide the RIF mixer with the LO we need? Unless D13 Varactor can really swing this oscillator when switched by the Aux position?

I havent looked at this in exhaustive manner, but appears you would lose 28 mhz if you have to use Q5 as your VCO oscillator for the AUX position. It seems to me there should be a spare unused FET based VCO oscillator with missing tank circuit components that the diode matrix would switch in when in the AUX position. As I say this is a first blush look and I may be missing something here. If you look at the TS820 VCO board you will see they have a extra VCO oscillator Q11 with the missing tank capacitors and tank inductor that is selected by the diode matrix when the band switch is in the AUX positions.

As I pen this it occurs to me that I have never measured the VCO output frequency in AUX position of the band switch. If you have covers off a TS830 you might want to do that. You do that by connecting your Freq counter to D40 on the PLL board and swing the VFO from 0 to 500. Would be interesting to see if it is different than the 28 mhz output frequency. There is some component difference if you look at the dc voltage from Aux. It applies the FET drain voltage thru D15 and there is an additional capacitor C32 in series with T5 tank coil. Not sure what this config does. If I get time I will look at VCO output of Q5 in aux position. Do it very regularly for 28 mhz during alignments, but never had occasion to look at it in aux.

I suspect you are looking at a TS-830M manual and schematic. There is no Q14 on the audio board of a TS-830S. Just white out or disregard the red voltages in this area on Kens large schematic.

Additionally read my first response again. List of TS-830 schematic mistakes have been posted several times on this reflector. If you are a student of the radios you will uncover most of them over time.

Bill:

I forgot that when you place rig in AUX position that the display blanks. That means there is no VCO output signal for you to measure at D40. That means that when you place rig in AUX that Q5 FET VCO Oscillator produces a VCO frequency that results in out of band operation. So VCO output is defeated by switches Q22/Q9.

I looked at the Q5 oscillator circuit a little more and that additional series cap would result in the total capacitance of the Tank being higher in frequency as capacitors in series are lower in value and would result in the parallel resonance with T5 tank coil being shifted higher in frequency.

If you want to look at the VCO frequency of Q5 you need to remove the blanking signal. You can do that by placing a jumper at Q21. Use couple of pins and grabber test lead and jumper from Base to Emitter of Q21. VERY IMPORTANT----Make sure you are placing the short on the correct transistor leads. This removes the forward bias on Q21 and turns it off. The VCO output line will no longer be shunted to ground and the display will illuminate and your counter at D40 will display the operating frequency of Q5. We know it is in the 35 mhz range on 10 meters and my guess is it will be higher perhaps closer to 40 mhz in AUX position.

I have covers on my two TS830s so cant do the test at this time and have customers TS520S on the bench. Do have a TS830 in the box waiting and if get time I will check Q5 output frequency in Aux position.

Once we known what Q5 does when band switch is placed in AUX position maybe we can work backwards from there to determine the range of the short wave frequencies that could be copied in the AUX position.

Again this is all based on it looks like Q5 is used both for 28 mhz and Aux band. Unlike the TS820 that has an extra VCO oscillator with no tank circuit C and L installed.

I saw no responses? I assume you still need help.

You need to adjust the bias voltage pot to set the resting plate current to 60ma if you can in SSB mode with mic gain turned down. If you cannot then leave the heaters off until you resolve this issue. You can also troubleshoot low or missing RF drive with the Screen Grid switch turned off.

I did not see a measurement of RF-1 on the AF board Conn 11 Pin 5? First thing to do if the ALC meter is pegged up scale. It should be approx 3.2vdc. This voltage powers the ALC bus and if no ALC bus voltage the ALC meter will peg up scale and you will have no dc control voltage to Gate 2 of your Q2 TIF amp and no RF drive voltage therefore no RF output.

You will need RF probe/.VTVM or O-scope to measure RF drive levels as noted on the TX Level Diagram in your service manual. Very easy to quickly determine where RF drive is missing so you can then concentrate troubleshooting efforts such as taking DC voltages at the stage or device.

Start with ensuring there is good RF-1 voltage on the Audio board. If no RF-1 measure 9vdc regulated. If good 9vdc then clean trim pot VR-3 and see if can set RF-1 to 3.2vdc.

Bill:

I think I went the wrong way on Q5 VCO oscillator frequency in the AUX bandswitch position. I think it goes down in freq from its normal 10 meter frequency and not up? In the 10 meter bandswitch positions Q5 output frequency is from 36.83 mhz to 38.83 mhz. So for example with the bandswitch at 28mhz and the VFO at 250 Q5 output freq would be 37.08 mhz. 37.08 - 8.830 = 28.250 mhz.

Retaining the normal 10 meter band coverage means that you must maintain tank circuit components T5, C31, C33 values as installed. With these same tank components when you flip bandswitch to AUX position then the output frequency of Q5 VCO oscillator would have to be approx 35.795 mhz to 36.235 mhz to cover the one aux band I think KW had in mind. If this is true then I think it is pretty clear why KW provided this AUX position on the TS530 and TS830 models and it has nothing to do with short wave reception. Look at this:

35.795 mhz - 8.830 mhz = 26.965 mhz or Channel 1
36.085 mhz - 8.830 mhz = 27.255 mhz or Channel 23
36.235 mhz - 8.830 mhz = 27.405 mhz or Channel 40

Look familiar! I think you previously asked me if it could be for 11 meters. Shame on them for not just saying the AUX position was for 11 meter band "receive only". Now the truth is you will notice L103 missing drive coil. on the RF board. Wonder what that is for? Sure aint for receive!

I wont go in to detail here how then to select L101 Ant and L102 Mixer coils for 11 meters.

Only other way I can see to copy any other shortwave bands would be to change out Q5 tank circuit components and then would lose 10 meters.

Of course I could be wrong but sure looks like with the way Q5 VCO is configured only use for the AUX bandswitch position is for 11 meter coverage. Measuring of Q5 output frequency in AUX position will confirm this. Next TS830 I get on bench will try to remember to do that.

Topic: 48361 Message: 48379

OK then KW wasnt being nefarious, but why not just say what the Aux position is for and how to engage it unless not wanting to make that known in countries where it was illegal? Could have used a disclaimer statement. Wonder if they sold a kit of parts in those countries? Here is an L101, L102, L103 and capacitor for Q5 VCO oscillator?

Most folks who mod TS530 and TS830 dont use the AUX bandswitch position as easier to just switch the BCD input from the counter to the 1/N feedback signal divider and get 11 meters coverage on 10 meters. Just have to do a little coil pack tweaking and good to go. If a non-ham they dont care if they lose 10 meters. Some will put in switch so can still retain 10 meters. This mod is well published on the web.

Again I am not certain but sure looks like what the AUX position is intended for. Still not certain what C32 does for Q5 frequency and if its value needs to be changed? Clearly will get a different output frequency from Q5 between 28 and Aux bandswitch positions as the circuit is built.

Bill\Terry and Group,

Hot off the email from Japan as we speak. The AUX is now a spare spot on the band switch, the design of the radio was when 11m belonged to the ham fraternity. When change came about, it was too hard for Kenwood, to redesign the the RF and PLL boards to cater for this, so they move the frequencies up one notch on the band switch, removing 11m. Now the hard part is getting the exact information. The Kenwood guy told me that the transformers are only a few uH different to the 10m band, but within the same range, the 10 m cans\formers are close enough and would be wise to salvage from junked RF board. A few "0" ohm resistors (links) and caps are required this will then complete the original design. Frequency range for 11m is 26.934.0 to 27.579.0 +\- 5Hz. He told me that the very first edition of the service\user manual had 11m included in the circuit diagram. He did not mention where it was located on the band switch. I have asked him if he has that diagram\service manual - not sure how long this will take to get a response as this took over 9 days to get a reply.

Sorry, I thought it had been made clear enough. I got the crystals manufactured fresh in the state of Oklahoma by ICM. They did a perfect job. The crystals have been swapped out and everything is working again on ten meters instead of eleven.

Appreciate the source, those were only a few dollars less than brand-new, and with shipping might have actually come out to more considering the costs involved getting across the big pond.

Incidentally, in the post about getting the crystals in, I wrote up a rather detailed and step-by-step procedure for pulling the oscillator board and replacing it with the new crystals in. If you need to do this some day and want guidance, three people so far have indicated that it is both correct and detailed enough to be helpful. I will take that as a sign that it isn't too poorly written. Hope it helps you, or someone else.

Thanks Dave

Now we just need to get your KW source to tell us all you need to do on the PLL is adjust Q5 T5 so you can get a frequency swing from 35mhz to 38mhz and we are good to go. I see that the tank capacitors are potted on the board in some kind of resin so not likely you mess with them. You can see that other VCO oscillators are shared between 2 bands and they have a 2 to 3 meg swing. I see different Varactor diodes used and some are even back biased. This means some will see an increase in freq with decreased varicap tuning line voltage and some will see an increase in freq with increase in tuning line voltage. Not sure why they do this. I need to make time to play around with the PLL board more.

As this is getting long and really more of an academic exercise now and not really interested in helping people to use AUX for CB band reception, Bill and I are taking off the reflector and will work on as time permits.

Thanks again

Craig

You are limited to what you can do with VCO oscillator Q5 which is shared for the 10 meters and Aux positions of the bandswitch. The output frequency of Q5 is 3 times higher than what you would need for 5 mhz. Would need a VCO oscillator in the 13mhz to 14 mhz range and even if could pull Q5 to that range would then lose 10 meters.

48389. TS-830S AGC problem

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-28 02:54:39 UTC
From: <guido@...>
Topic: 48389 Message: 48389

I had my TS-830S just sitting there listening to a SSB net while I was working, and the audio stopped!

The s-meter still works, i.e. fluctuates with signals and the calibration signal, but there is no audio out, unless the AGC is on OFF. The radio appears to work correctly, (I haven't tried transmitting.) but there is no audio unless the AGC is OFF.

I've poked around and checked the voltages on the IF board, and they appear OK. I've followed the calibration signal thru the board, but it goes off when you switch the AGC to FAST or SLOW. I'm not familiar enough with the circuitry to determine where the problem is.

Can anyone suggest where to look next?

Thanks,

Bill

48390. Inexpensive Digital RF Millivolt Meter

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-28 12:13:56 UTC
From: <wagstw46@...>
Topic: 48390 Message: 48390

I bought a digital RF millivolt meter off Ebay ($41.00 shipped). I did this for a friend to evaluate it for him and will be shipping it to him.

You can view it here: 281216433787

I have not performed an exhaustive evaluation but did compare its accuracy to my calibrated Boonton 92E. It is shipped no cost from China. There are no instructions with it. You plug the display in (must orient correctly but no big deal). I powered if from 9vdc from my bench supply. Just 4 connections plus and minus dc power and RF in and ground.

It has a nice bright blue display with protective plastic over it. It displays dBm, millivolts, and power.

I drove it with calibrated RF sig gen. I did so with the input terminated in 50 ohm load and with it un-terminated. In both cases it did not read correctly. You must use the Function key and the Set key to either Plus or Minus a dBm offset. Very easy to do.

Once that is done it reads close and seems to track. It is advertised to read from 1 mhz to 500mhz. I did the testing at 14.200 mhz, but did run up higher just to confirm it can read 2 meters for example.

It is also advertised as having a range of -80dBm (22uv) to 10 dBm (707mv). Mine crapped out at around -70dBm. A little disappointed about that. Not often you need to read levels this low other than would be nice to accurately read -73dBm (50uv) from your RF Sig Gen so you know you are using level needed to cal your KW S-meter. Of course you can read higher than 10dBM by using a step attenuator at the RF input.

I printed the specs provided by the Seller in his Ebay listing. That is the only documentation I could find. No schematic, no circuit description etc. I suspect it may be based on Wes Haywoods W7ZOI popular RF power meter that uses a AD8307 log amp.or perhaps a later version chip?

So I am Not Endorsing this unit, but if you have no VTVM and RF probes and want to be able to measure and adjust KW hybrid RF voltages such as Carrier Osc, Het Osc and VFO output this meter works just fine. Certainly cant beat the price. It could be placed in a nice bud box. I did not measure the power consumption so not sure how long a 9vdc battery would power it.

Terry K9TW

Done with my coffee and heading to the bench so customers dont think I am a slacker!

I know you say you have normal S-meter function in Fast and Slow, but humor me and do this:

1. Measure the AGC bus voltage at IF board Conn 15 Pin 3 with high Z meter (VTVM or DMM) in Fast or Slow. On dummy load it should be 3.6vdc, but your meter will pull it down to approx 2.6vdc or so and should cause S-meter to move up scale. Make sure you are on Pin 3 as there is 300vdc on Pin 1.

2. Again make certain on Pin 3 and connect 3.0vdc to Pin 3. If no bench supply then couple of flash lite batteries in series. Minus to chassis ground and plus to Pin 3. This should power the AGC bus on hard and keep the IF amp mosfets turned on. See if you get your audio output back with stiff 3vdc applied to the AGC bus.

The only thing that should happen when you turn AGC OFF is bias off Q10 AGC amp so it cannot pull the AGC bus voltage down. Now only control of the AGC bus voltage should be the RF gain pot that powers the bus thru RFG.

Well, I too had my first cup and attended the daily status report for work, so everyone thinks I'm working.

I measured the voltage at pin 3 of connector 15 with my Tektronics RMS DMM. With no signal to the radio, I measured 3.00x volts on the pin in all positions of the AGC switch. The meter did go upscale when I measured the voltage, and the upscale reading was the same for all positions of the AGC switch.

I did not see where connecting 3.0 volts to the bus would accomplish anything, as that's what the reading was. But if you feel that will provide additional information, I will do it.

Thanks for the reply, and what should I try next.

Bill

Terry's posted prompted me to post about a much older (around 1964) RF voltmeter that I picked up on eBay last week:

http://www.ebay.co.uk/itm/Electronic-voltmeter-by-G-E-Bradley-complete-with-RF-probes-etc-/201048437459?_trksid=p2047675.l2557&ssPageName=STRK%3AMEWNX%3AIT&nma=true&si=6EWBVimHzkpXlrfiT4Sy3xwrgGE%253D&orig_cvip=true&rt=nc http://www.ebay.co.uk/itm/Electronic-voltmeter-by-G-E-Bradley-complete-with-RF-probes-etc-/201048437459?_trksid=p2047675.l2557&ssPageName=STRK%3AMEWNX%3AIT&nma=true&si=6EWBVimHzkpXlrfiT4Sy3xwrgGE%253D&orig_cvip=true&rt=nc

I was also able to download the manual and circuit diagrams from VMARs site, and also read posts about various common problems with this meter and how to fix (most problems seemed to stem from screened Germanium trannies going short-circuit).

Functions as full multimeter but I only bought it for the RF volts measurement.

Well to be honest I haven't had chance to test it on my TS520SE yet, but it looks like it's in perfect working order and just a pleasure to use. Even the mechanics of the sprung hinge case neatly holding the RF probes (terminated and unterminated, and one for 400V) are a delight. It smells of old aircraft when you open it up and breathe in!

It had sealed stickers on it showing it was in RAF hands (UK equivalent of USAF) till at least 2008, and was calibrated then by an instrument calibration outfit who are still around. It has an internal 12V DC calibration and that works fine, as does measurement of any resistors I've tried it with. All the zeroing controls operate OK.

So if you see one of these around (goes under the original military spec of CT471) and you can verify it works, or is cheap enought o take chance on it like I did then it shows there is plenty of utility in older instruments too.

Brian,
Yes, but I would suggest a good AB switch like an Alpha Delta. Don't use one of the cheap ones as you might have problems with RF feeding back into the unused radios front end.

Topic: 48392 Message: 48396

I'm with my friend Mark on this one. Besides the aforementioned Alpha Delta units, the old Heathkit HD-1234 coax switches work well. I have two in line now to select among radios, antennas and my dummy load (a Heathkit Cantenna, of course). Oh did I mention that I used to work for Heath?

The "ne plus ultras" of mechanical coax switches, however, are made by Bird Technologies (y'know, the wattmeter people). New ones cost slightly less than an automobile, but used ones show up from time to time on auction sites. Prices are in the "whatever the market will bear" range - $65-$100 at the low end up to $500 or more (check it out; I'm not kidding).

Whatever you do, DON'T get a blue or greenish painted, re-branded one that's made "over there - WAY over there" and costs 20 bucks or so. I had two of those things some time ago and they both literally fell apart internally.

73,

Craig

Topic: 48398 Message: 48398

Greetings Group!

I hope all of you are doing great so far into this new year.

It is rather distressing that newly approved members fail to read the "auto-send msg" that is generated, and sent to ALL new members upon approval of membership to this group, regarding the requirement(s) for identification when posting msg's and/or questions. They request help regarding various "problems" that are plaguing their rig(s) which is the purpose of this group. It is suspect that IF they can not read and adhere to the groups simple rules/policies, how can we expect them to possibly follow possibly complicated diagnostic instructions?

The moderators and myself, try to do a good job keeping the group safe, sound, interesting,
and free of QRM/QRN. The rules/policies are CLEARLY stated. This seems to be a continuing problem. It will be no longer. All new/newer members or, any others that are "moderated" or otherwise restricted in regards to posting privileges...take heed...this also includes the "old timers" who are "un-moderated,".....

IDENTIFICATION IS MANDATORY.....see group home page for further explanation

We now return to our regular programming.....

Topic: 48399 Message: 48399

Greetings Group,

It still seems that there is some confusion.

Go to this groups home page, under the picture of the wonderful Kenwood station, click on "FILES." Look at the third file down: "AUTOTEXT MSGS."
Click on the first one. It clearly states this groups rules/policies regarding the aforementioned
topic, which is "auto-send" to EVERY new member, upon approval of membership.

Mike-w5rkl(group moderator), and myself, Joe-wb7uqu(group Co-owner), spend a great deal of time having to deal with such things.

Thanks for your attention regarding this matter....we now return you to the regular program

A good multi connection coax antenna switch will ground any SO-239 socket that is not in use or selected. If, for example, the coax switch has 6 settings and the switch is set to position 2, the center and ground of each SO-239 in positions 1, 3, 4, 5, and 6 are connected together, i.e., grounded. Therefore, any radio connected to the unused/unselected switch positions will have the SO-239 center and shield connected together. The coax switch should be connected to the shack's ground. Don't rely on the 120VAC "safety ground" to be used as your "shack ground".

I have and use the MFJ-1701 6 position antenna coax switch and have never experienced any failures in any radios connected to the MFJ-1701 coax switch due to high levels of RF from 100 watts or higher, and that includes my Yaesu FT-857D and FT-757GX that are connected to the MFJ-1701!

Notice Mike mentions a "GOOD" antenna switch. Most of the commercial ones you buy today advertise an isolation spec of greater than 50 dB and should be just fine unless you mis-configure them.

What does 50 dB isolation mean?

It means that if you connect a dummy load to Port 1 and connect your rig to the Common Port and apply 100 watts into the Common Port which is approx 70.7 rms rf volts you should see no more than approx 223mv rf volts at Port 2, Port 3, Port 4 or any of the other grounded ports.

I like Mark prefer to use the Alpha Delta switches for several reasons. The switches have very good positive detents, they advertise greater than 50dB isolation, and they have a replaceable gas discharge arc gap built in. Not cheap but good quality.

I have measured my AD switches at 14.2mhz with 100 watts input and I get approx 120mv rms at the open ports which is 55dB isolation. So they meet the advertised spec. Now what does that mean for another receiver connected to that port? Well full scale S-meter deflection on most Kewnwood hybrids occurs with approx 3mv at the SO-239. So 120mv is still a pretty big signal for the front end of any receiver. It would peg the S-meter hard, but should not burn out step up transformers like L41 or the RF amp mosfet.

The key is dont rely on antenna switch port isolation. Never configure any antenna switches that would allow you to accidentally transmit into the front end of another connected transceiver or receiver.

Years ago antenna switches like B&W and Heath might even have the dB isolation spec on a label on the switch case. So if buying at hamfest see if there is anything about port isolation on a label affixed to the antenna switch.

Personally I would stick with the "Good" name brands today as Mark and Mike suggests. I would be pretty nervous about CB antenna switches, hamfest specials, or homebrew switches.

If you have a Heath VTVM and RF probe or O-scope suggest you test your new switch before using it. Just test as stated above with 100 watts and dummy load and measure the RF voltage at unused ports. If you read more than 223mv at a grounded port it means you have less than 50 dB of isolation and maybe need to think about how you plan to use it. It would be fine for a single transceiver and a dummy load and couple of antennas.

One thing I forgot to mention that grounded means for DC and may not mean same the thing for RF especially as you move up in frequency. Really depends on lead lengths and lead dress inside the switch. Of course it can mean pretty much nothing for lightning especially if havent taken precautions outside the house.

Also, dont depend on the fact that the 2nd transceiver is turned off to protect it when transmitting on the 1st rig. The front end will still see whatever RF voltage is presented at the switch port.

If you do not have any means to measure the RF voltage at the other ports you can turn your 2nd rig on and while transmitting on the 1st rig at 100 watt output level see what your S-meter does. I would test on all the bands, but with emphasis on 10 meters. I would be surprised if you did not see S9 +40 or what ever max is for the transceivers you are using.

Oh and the switch wafer should be made of Ceramic not the same material the band switch and Mode switch wafers are made of.

There's a cheap 3 position coax switch, the Workman CX-3 3 position coax switch that is priced between $10 to $35 and is being sold on ebay. The front cover says it is rated at 1KW. I have one of these, bought it a few years ago to see what it was made of. It's cheaply made, the wafer switch is made of the same material the Mode and Band switch wafers are made of, and the unselected SO-239 sockets are NOT grounded, even in the "OFF" position!!! I would be very leery applying 100 watts to this switch and clearly I would NOT apply 1KW as the front panel says!! The detente is soft, very mushy and no clearly defined solid detente, when brand new! The only good thing about this switch are the 4 SO-239s you can remove and use elsewhere.

The make and model coax switch you chose is entirely up to you.

48405. KENWOOD HYBRID NET UPDATE (March 30, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-30 23:24:19 UTC
From: Mark Gilger
Topic: 48405 Message: 48405

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Dayton Hamvention Kenwood Legacy Forum:
This year will be the first year for the Kenwood
Hybrid Legacy Forum to be held at the Dayton
Hamvention. The forum will be Sunday May 18th.,
room #2, 10:30 □ 11:30. The following preliminary agenda has been proposed:

* History of the legacy products.
* Resource help with parts, documentation, etc..
* SDR integration into the legacy line.
* Rewinding a TS-830 L41 coil.
* Tips & Hints.
* Questions and Answer Technical Session
We hope to see you there.

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

Jimmy, WB2KNR ran the Saturday 40 meter net. He
had 21 stations checking in under good band
conditions. There were 6 new stations checking
in, WA3VZK, KT3E, KC2MMC, WD4DMZ, KA1WVM, and KB4ZTK.

We had the following number of radios checking in.

3 running TS-520(x)
4 running TS-530(x)
2 running TS-820(x)
4 running TS-830S

He was running his TS-520.

The Sunday 20 meter net we had 11 check-in under
poor band conditions. There was 1 new check-in,
AF7CY. We had the following number of radios.

3 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
2 running TS-830S

I was running my TS-940s.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 82, Sunday□s total = 73 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

73's,
Mark, WB0IQK

From: Joseph Stiles
Topic: 48407 Message: 48408

First, obtain the owner/operators manual and READ it multiple times. These radios are not plug-n-play. You will be required to "tune it up." Find yourself a "dummy load" capable of handling at least 100 watts. You don't want to be causing interference.
Novice/Tech are allowed to operate Phone/Voice on 10 Meters between 28.300mHz and 28.500mHz

Also, PLEASE read the "auto-send" message your received when your membership was approved regarding proper indentfication

 In short: Your post(s) are required to be signed with your First NAME & CALL SIGN (if any)

Mike,

I'm not sure what you are asking. If you just want to listen until your get your license...you can erect a simple long wire antenna around the inside of a room and plug it into the middle of the antenna connector on the rear.
DO NOT ATTEMPT TO TRANSMIT WITH THIS ARRANGEMENT.
Daytime usually favors higher frequencies, night time tends to favor lower frequencies.
There are exceptions...but don't worry about that now.
Start scanning around, you'll be surprised what you can hear with a simple wire antenna.

Please remember to properly sign the end of your post(s)

Mike,

It would be helpful to know what you know about basic electronics and/or this radio in particular.
A good basic "eyeball" inspection should be the first step BEFORE you turn on the power. You can avoid potential problems. If you have already applied power...and no smoke...that's good, but you should still do a good visual inspection of the inside....top and the underside. You are looking for melted/overheated wires, various capacitors leaking...especially the two tall high voltage power supply ones. These are readily visible on the top side..in the middle. Most of the time they are black...but I've seen some grey ones. Other things like, various critters that may have made a home in there. Since you have an 820, make sure that the "shorting plug" is in the 9 pin socket...or that holes 8 & 9 are jumpered together...if it is not there...the radio won't work.
There is an explanation regarding this on the manual.
If you are in an area that has a radio club...go make friends..I'm sure they'd be happy to help
you.

Mike,

Also, take a look at Ken Kemski-k4eaa web site...lots of real good info for the beginner including simplified "tuning instructions."

Take a look also at: www.wb4hfn.com more good info and good copies of manuals for free download

I hope you learn to enjoy the both hobby and the group. I have been
licensed now for about 55 years and still love it!

Yes, there is one thing I try to remind new comers about: Never forget
that there are LETHAL voltages inside your transceiver, and they don't
disappear immediately after the radio is turned off...even on receive!!
There are procedures to follow if you ever need to remove the covers for
discharging the high voltage capacitors safely. There is a meter on your
rig and one scale shows High Voltage....notice it goes up to over 900 volts!

Try to get a hold of an older, say pre-1975 ARRL Handbook. They had good
explanations for vacuum tube output sections and high voltage
explanations. Also how to tune one up. These radios are not "plug n' play" !

Have fun

Bob / WA2JAJ

Hi Mike?
First thing to do is find the SG switch on the back of the rig and make sure it's in the down position. Same with the HEATER switch on the front panel, bottom right.
This will prevent accidental transmission. Belt & braces.

Lethal voltages inside. Read the manual and have fun. We all had to start somewhere!

If Mike's basic electronic knowledge is lacking, may I suggest he check my website:

http://w5rkl.com/basic-electronic-videos/

I have a few basic electronic videos that show how to calculate resistance, current, and voltage in series, parallel, and series/parallel circuits using Ohms Law.

There's a video that shows how to calculate the cathode voltage based on a level of cathode current. You can change the cathode current to any value and perform the calculation as shown on the video to achieve different results. This video also shows how to calculate the voltage drop across the meter multiplying resistor, 3.3K in the case of the 520 and 820, and using that value to determine what the voltage will be that is applied to the IP meter.

Understand, when you watch the cathode IP meter circuit video that the 600 ohms used for the meter's internal resistance will vary some what from meter to meter and the cathode resistors, in real time, will not always be exactly 10 ohms. However, for the purpose of the video, the meter's internal resistance is assumed to be 600 ohms and the cathode resistors are assumed to be 10 ohms.

Hi Mike,

I'm not sure I understand what you are asking when you say,

"is there a basic affordable mode of radio one might suggest"

Also, may I suggest an excellent and easy to read book on learning electronics, including vacuum tubes. You will need to have a solid understanding of vacuum tube theory especially when troubleshooting the driver and final amplifier. The book I am referring to is

Basic Radio Course by John T. Frye

This book is out of print but it can be found quite often at your local public library, on the web, and on eBay. There is a seller on eBay who is selling this book burnt to a CD for, if I remember correctly, $9.99 plus a few dollars shipping. I highly recommend it. The seller on eBay is selling the 1951 edition of the book but the date doesn't diminish the subject matter at all.

You also might look at a used book store, that's where I found my hard cover copy for $2.00.

As Dave said, older copies of the ARRL handbook are also good learning tools.

Another source is William Orr's Radio Handbook. You can find that book on eBay.

I forgot the mention, you will need some test equipment. If you have never used test gear such as VTVMs, signal generators, frequency counters, then I suggest you watch my video that covers basic test equipment. All of the test equipment shown in that video was purchased on eBay, except for the calculator.

I also have a video that shows a simple series circuit (resistors in series across a 12 volt source), that shows how to calculate and use a DMM to measure the voltage drop across a resistor and the voltage that will be present at the junction of 2 resistors. Unfortunately my camera quality doesn't allow the resistors to show up but trust me, no I'm not a use car salesman, the resistors discussed in the video are actually there.

48419. Kenwood mic connector tip

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-03-31 13:31:21 UTC
From: <crgrbrts@...>
Topic: 48419 Message: 48419

This past weekend my TS-530S began acting silly. Suddenly, the T/R relay started to chatter incessantly, the problem exacerbated by switching modes during the tune-up process or touching the MC-50 microphone's connector (a clue!!).

As one might suspect, the culprit was, indeed, the mic connector. A disassembly and inspection revealed a loose PTT wire with maybe a wire strand or two left soldered while the rest of the wire strands were free to flop around, making tentative contact with the connection next door. The remainder of the connections pretty tenuous, too.

The cure, obviously, was to re-solder the mic cable and connector. What could be easier?

Yeah, well, I suppose it's easy if you're a world renown neuro or vascular surgeon, but for an old hand (literally) like me, the operation is-- shall we say -- a "challenge." The four mic cable wires in question seem to be about 28 gauge with mysterious, nearly microscopic nylon filaments intertwined with the thinner-than-human-hair copper wire strands. If one is to achieve a good soldered connection, these filaments must be separated from the wire strands and removed. This process is tedious and "fiddly" but not unduly difficult. The real challenge is soldering the very thin wires onto their respective connections. The wires tend to flop about as the mic connector body skitters away. While an apparatus such as a Panavise parts holder can be a huge help in stabilizing the components, there is another way, courtesy of a little tool I found purely by chance at my local hardware store this weekend.

While perusing a hanging display near the store's checkout counter, I spied a thingie called a "Heat Resistant Soldering Tweezer" distributed by the ubiquitous Enkay company of Brooklyn, NY. This nifty $3.00 tool acts as a mini clamp to hold the wire to be soldered onto its connection. Solder does not adhere to it, so the connection can be made very easily and securely with little of a cold solder joint resulting. Oh, I keep the mic connector in place on my work table by simply taping it down. Even with a Panavise parts holder pr similar apparatus to hold the mic cable and connector in place, the soldering tweezer can be very useful.

(This is not a plug, but) Enkay publishes a 40-something page catalog of cool stuff. It can downloaded from their Enkayproducts.com website.

I meant to say "...with little CHANCE of a cold solder joint resulting."

(I also meant to say: "The remainder of the connections WERE pretty tenuous, too.").

To make this post even marginally worthwhile, here's another handy hint (though I've passed this one along before). To clean tube sockets -- such as those under our 12BY7 and 6146 valves -- use "interdental brushes" moistened with DeoxIT or other favored contact cleaner. These tiny nylon brushes are mounted on flexible wire shafts, making them perfect for cleaning sockets and hard-to-reach contacts. They're readily available in the dental care aisles of pharmacies.

These are typical of what I'm talking about. I use the little disposable ones packaged in the multi-packs:

http://www.gumbrand.com/between-teeth-cleaning/interdental-brushes.html

The latest issue of QEX magazine -- an ARRL publication -- contains an interesting article by Michael Dzado, AC0HB.

The title and subtitle tell all:

"An Eight Channel Remote Control Antenna Selector: Select between eight antennas or feed one antenna to any of up to eight radios. With better than 70 dB of port-to-port isolation, you can be sure the signal is going where you want it to."

If you're an ARRL member you can download this as a "sample article" in PDF format by visiting the QEX webpage on the ARRL.org site.

Topic: 48423 Message: 48423

Meter shunt resistors replaced, idle plate set at 60ma, pin 5 final tubes -104 rx -59.9 tx.

3.2 volts connector 11 pin 5 rf1 on af board, connector 9 pin 1 alc from q31 2.59 volts.
if board connector 14 pin 1 alc from af 2.59 volts
to bring both pin 1 voltages up to 3.2 volts pin 5 is at 3.8 volts, left pin 5 at 3.2 volts via vr3. vr3 is smooth thru adjustment.
when I raised pin 5 voltage to 3.8 volts receive audio came up with it.

receive works great on all bands, s meter functions as it should, reduction of rf gain brings s meter to full scale plus.
once I set idle plate at 60ma turned off sg switch and heaters, all voltages on usb meter on lp
now I have no alc.

thanks,
Ira L. Parker

Ira,

I could be wrong but it appears you are saying that you set the SG and Heater switches to OFF and now you are saying you have no ALC, assuming with the transmitter keyed in TUNE mode. Is this correct?

From: Terry Wagoner
Topic: 48423 Message: 48426

Ira I work with many people at the same time so hard to keep my rigs straight as time elapses between email exchanges.

OK when you say you have 2.59vdc on Conn 14 Pin 1 on IF board rig need to know what conditions this measurement is made at. Heaters on, Tune mode, Flip to Send. CAR Level pot advanced, Drive control peaked.

If you have RF1 adjusted to 3.2vdc then you should see approx 2.6 vdc on the AGC and ALC bus at the respective molex connector pins on the IF board. The reason is due to the impedance of your meter pulling the bus voltage down. When you key the rig if there is correct RF drive and control grid operating bias the ALC bus will drop from 2.6vdc to approx 2.0vdc and the meter will drive up scale.

The meter circuit Q7/Q8 is shared in receive and transmit. In receive mode RL-1 contacts measure the AGC bus voltage and in transmit the contacts switch and measure this ALC voltage supplied from Conn 14 Pin 1. If you have good S-meter action in receive mode it tells you that the relay normally closed contact is good. If you have no ALC indication in Tune mode while loading the rig and you do have approx 2vdc at Conn 14 Pin 1 then it means the normally open contact of RL-1 is dirty/bad. RF drive is producing positive grid current and turning on Q31 ALC amp and pulling the ALC bus voltage down, but the meter doesnt see it as relay contact doesnt power the meter circuit (the gate of Q7 FET).

So I dont understand your final sentence. It sounds like the AGC bus is powered as it should be from RF-1 as evidenced by good S meter action and proper RF gain action. When you measure AGC bus your test meter (dmm?) pulls the voltage down from the 3.2vdc level that you have set RF-1 to and that is normal. Test meter wont pull RF-1 down as it is a low Z power supply.

You then state you can set zero signal resting plate current to 60ma (that is good). The rest of your sentence makes no sense to me. You turned off SG switch, you turned off the Heaters. You then say all voltages on USB. Are you trying to say you measured the final tube cut off and operating bias voltages in USB position of the mode switch and the meter in the Ip position? Doesnt matter what position the meter select switch is in to take voltage readings. I take voltage readings in CW mode as that is where KW took them that you see on the schematics.

I have tried to tell you the things you need for ALC indication to load rig in TUNE mode.

1. Must have operational bias of approx -60vdc.
2. Must have rf drive voltage that exceeds that level of dc bias offset on the positive going peaks for the envelope. Must have positive grid current to cause ALC amp Q31 to pull down the ALC bus voltage.
3. Must have RF-1 voltage set approx 3.2vdc
4. Must have ALC bus voltage supplied to IF board Conn 14
5. Must have good RL-1 relay contacts
6. Must have good Meter driver circuit (we know you have that as the S-meter works in Rx mode).

The typical reasons for no ALC indications in Tune mode are bad RL-1 relay contacts and/or low RF drive level to control grids of the finals. Low RF drive can be bad driver tube or bad band switch contacts. If no ALC on any band not likely the bandswitch.

Go thru this list and check off what you know for certain that you have.

For ALC indication you do not need the SG switch turned on. You can test ALC with Heaters on , Mode switch CW, CAR pot full clockwise, Flip to Send, Drive control peaked. If no ALC indication then check steps above. You report that you have 1, 3, 4 , and 6. I do not know about 2 or 5. Number 2 requires VTVM/RF probe or O-scope. 5 is not easy to clean the contacts and typically will not last very long if you do.

No problem Terry. I didn't understand what Ira was saying.

Ira, I could be wrong but from what I read in your posts it appears you turned both the SG and Heater switches OFF. If this is what you actually did then the reason you don't see any ALC is because you turned the "HEATER" switch OFF. If the Heater switch is turned ON but the SG switch is set to OFF you will still see ALC.

I'm new to the group and want to say thanks for all the great info available. I'm working on a 520 belonging to a local ham. My test equipment includes a VOM and an O-scope which I'm still learning to use. I have a couple of generic questions:

Can someone tell me what the designations (Y), (GR), etc. indicate on the 3SK35 MOSFET's? The NTE cross-reference pointed all to the NTE222. Dots on top seem to coincide with color.

Also, when checking voltages per section 8 of the Op Manual, are these all with reference to ground as opposed to one lead to another?

I'm quickly becoming another fan of the Kenwood Hybrids!
Thanks again,

Hello again group.
I know this is probably a long shot, but here goes. I recently acquired a TS-520SE. While going through it, I found the slugs and the actual coil forms themselves destroyed on some of the ANT Coil Unit coils - looks like excessive heat was applied to the coils.
So I'm in need of the 160 meter and 80 meter coils on the Ant Unit Board - I believe they are designated as L1 and L2. If anyone has these around in their junk box, (or the whole board for that matter), I'd very much like to hear from you.

Subject: [TS-520_820_530_830] TS-520 MOSFET

I'm new to the group and want to say thanks for all the great info available. I'm working on a 520 belonging to a local ham. My test equipment includes a VOM and an O-scope which I'm still learning to use. I have a couple of generic questions:

Can someone tell me what the designations (Y), (GR), etc. indicate on the 3SK35 MOSFET's? The NTE cross-reference pointed all to the NTE222. Dots on top seem to coincide with color.

Also, when checking voltages per section 8 of the Op Manual, are these all with reference to ground as opposed to one lead to another?

I'm quickly becoming another fan of the Kenwood Hybrids!
Thanks again,
Charlie - AC6ZX

Charlie :

The designators are important and not just hieroglyphics!

They tell you what the Idss rating is for the FET. Idss is the maximum drain current with zero gate bias.

Y is the lowest, then GR, then BL. For example for a 2SK19 the designators are as follows:

Y = 7ma Idss
GR = 14ma Idss
BL - 24ma Idss

So when replacing one with a NTE sub you can just trust that they have done there homework and that the cross reference is conservative for all operating parameters or you can look at the data sheet for the original mosfet you are wanting to replace and make sure sure the sub meets and exceeds the Idss rating. I prefer to study the data sheet if can find one.

As far as experience goes I have had good luck using the NTE subs. I also use NOS 40673s for the RF amps and they work well.

Hi - 1st post here, recent subscriber the last few months, but an avid reader. I have new to me TS-820s from the usual auction site. It seems to work real well (though I've not been able to test other than with a dummy load - no license yet, this weekend I will be passing the exams). The seller was right up front with the one problem that the rig has - the LCD kind of flickers, kind of not displays the correct read out until it warms up, about 5 minutes. Then, it works just fine. This happens no matter what band is selected. The display will read 9.1XX.X, 19.1XX.X or 29.1XX.X, no matter what you do. I.E., if 14 MHZ is selected with the band switch, the display actually reads 19.1XX.X (where XX.X is either a 0, 1, or 2 - nothing else). Ditto for 21 or 28 MHZ, read out is 29.1XX.X.

The seller assures me that the radio works fine in this condition, just the read out "flickers" until it warms up. I verified the correct read outs after about 5 minutes.

Any ideas why? Dirty switch? Something else as simple, hopefully?

Les

Updated the software to include a power/swr meter. Select-able power levels (160, 320, 600, 960,1280, 1600) for the meter.
Uses a Wavenode HF-1 coupler....
5 memory channels.....
5 or 7 inch screen (this pictured in photo section is 5)
Direct frequency entry via usb keypad.....

Topic: 48440 Message: 48440

Hi Terry and Mike,
Sorry for any confusion. I ask about posting to the reflector or sending e-mail direct to you. Your answer was to use the reflector unless the thread got to long or parochial. Hence I posted to the reflector and copied to you also. In the future I will post to the reflector only to keep the confusion down I know your a very busy man. ok. back to the problem at hand.

Previous e-mail:
terry= test af board conn 11 pin 5 rf1 on (3.2 volts), conn 9 pin 1 alc from q31 (2.59 volts), test If board conn 14 pin 1 alc from af (2.59 volts)
These voltages were tested using a dvm (10meg input impedance) in usb mode, htr off, sg off, meter lp. Then set mode to tune, htr on, sg on, meter to alc, peaked drive for max s meter deflection in rx, flipped to send no alc.

previous post reflector:
I think the first part of this post answers yours and mikes first questions. Second part 1-6.
1) 60ma
2) ? pretty sure I have an rf drive issue we'll get to that.
3) 3.2 volts
4) 2.59 volts (draw down dvm)
5) new rl1 relay from k4eaa
6) good s meter all bands, full scale deflection rf gain at min

final and driver tubes purchased from escr in Orlando. Getting to the rf drive problem, are there any other voltages I should check before starting to test for rf via the level diagram that will confirm this, like maybe the driver tube pin volts or other readings on connectors of the if,af or rf boards. I've got access to a o-scope waiting on model number to see if it will cover hf freqs and if the probes are with it. I'm soldering up a rf probe for my dvm also .01 cap, diode and 4.7 megaohm resistor. Not sure how accurate it will be but should be able to trace some until I get the scope. When tracing the rf should I be in cw, htrs on, sg off, car 12:00, drive 12:00?

Thanks once again for your patience and understanding

Ira L. Parker

Les,

Best of luck on your exam...you sound very confident that you ARE going to pass.

It sounds that you may have a problem in the DG-1 unit. That's the box that the digital display is plugged into. It has plagued many an 820S owner. Sounds like it's a thermal problem regarding one or both of the boards in the unit. I had a problem very similar to your on an 820S here, display refused to work correctly...showing 9.000 or 19.000 or 29.000 until it got warm..then started working fine. First, I would try removing the DG-1
unit. Make sure rig is OFF and UNPLUGGED...and check for HV around the HV power supply caps...the two round things..kind of in the middle of the rig...just to be safe..as there could be 900VDC lurking..as well as some lower but just as dangerous volts around.

Make sure to have some contact cleaner available. Remove and open up the unit, you will notice 1 board on each side...they are connected by "through pins." Remove the boards and clean ALL contact and pin surfaces. BE very careful when removing...as they can be a bit stubborn.
Make sure when re-assembling that each board goes back to where it originally came from. Reassemble and try out unit. It may now work just fine. If not, then you will have to do a bit
more surgery, soldering wires through about 18 or so "through holes" on the counter board. No difficult..just a pain. Kenwood put out a service bulletin about this many years ago.

My display was fixed after soldering wires in the "through holes."
The display is not necessary for your rig to operate properly.

Ira:

OK I dont remember telling you to copy me on email, but if I did I should not have.

What I meant to say sometimes if the thread gets too long or as you say of very narrow interest to a small audience or you are not getting the help you need here it is OK to email me off the reflector. To your issue:

1. Did you try with the CAR LEVEL POT advanced full CW ? If not do so.

2. Your homemade RF probe if configured like the N5ESE design will be accurate enough for TX Level diagrams. Really need a single diode and a 3 diode probe.

3. The TX level diagram is best run on 14.2mhz in CW mode with the SG switch off and the Heaters on. Can be run on 3.5 or 7 mhz if you have low bandwidth scope.

4. Best to first load to full 100 watts out if you can and then flip SG switch off and run TX level diagrams as you then will have the Mixer and Drive tuned circuits peaked. If cant load then just peak the Drive control in Rx mode or use the Marker signal.

5. Can start at TIF output at the IF board and work way to the control grids of the finals or just start at the control grids and work back to TIF amp. A quick check at the 6146 control grids would include measuring the dc operating bias voltage and then the RF drive voltage. Must have proper delta for grid current and ALC indication. Should see approx 45 to 47 rms rf volts. Should use a 3 diode probe or O-scope to measure the RF voltage at control grids or plate of the driver tube as the level is too high for a single diode probe and will burn out your probe. You wont be able to measure TIF with your RF probe as it is low approx 10mv. Should be able to read it with your O-scope.

6. YES you can measure DC voltages at the Driver tube and the Finals absent an RF probe or scope, but easiest way to trouble shoot loss of ALC indication and/or loss of RF output is to measure RF voltages and where you find them missing or low then reach for DMM or VTVM and check dc voltages at that device. Best way to measure Driver tube voltages is with a Pomona test socket. Absent that you can pull the tube and take the measurements in the socket pins. Be careful as you have 350vdc close to base of the tube.

7. If you have approx 2.6vdc to 2.9vdc ALC voltage (will be lower than 3.2 RF-1 due to the meter you are using) at the IF board Conn 14 and a new RL-1 relay installed you should have required dc control voltage at Gate 2 of your Q2 TIF amp mosfet and should have 8.830mhz TIF signal at output of the IF board Conn 6 and input at the RF board Conn 7 unless you have bad/dirty molex connector at either place. Can carefully pull and clean these two connectors.

This is about as far as I can take you. Mike W5RKL and Dave VK5PDL have the knowledge and experience to help you. Dave owns and works on TS530s.

I am swamped with work here at the moment so cant commit much time here.

Terry K9TW

Greg,

What pieces of test equipment do you have? You will need more than a cheap hardware store VOM to service your TS-530.

What level of electronic knowledge do you have?

What troubleshooting and repair skills do you have?

Do you have the TS-530 operator and service manuals and if so have you studied them?

Have you checked to ensure the IP meter indicates 60ma of idling current with the transmitter keyed in USB or LSB mode? This will tell whether current is flowing the final tubes or not.

Have you checked the group's "File" section, searched the message archieves for similar problems other members have had using the group's search feature? You have to log onto the group's homepage to use these features, you can't do it through email.

48447. TS-520 S S-Meter deflects full scale and stays there, when set to receive WWV

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-02 17:33:37 UTC
From: Henry Stephan
Topic: 48447 Message: 48447

Dear Members

I hope you can assist me.

I have a TS-520 S with an S-meter fault only whilst using WWV. When using the traditional ham bands, the S-meter works correctly.

On the other hand however, when WWV is selected, its needle immediately deflects completely across to the right hand side of the meter. It does not matter whether the AGC switch is set to slow, fast or off, with WWV it still deflects 100%.

However, with the AGC set to slow, it moves across slowly. With the AGC set to fast or off, it moves across quickly.

With the AGC line disconnected from the RF board, the problem disappears.

The connected AGC line into the RF board registers 3.0V, without RF signal, on each of the ham bands. With my signal generator connected, and an S9 deflection, the AGC line drops to 2.1v

In the case of WWV though, the AGC line sits permanently at 1.2 volts, even when my signal generator is connected.

I hope someone can assist in pointing me in the right direction of how to fix this fault.

Your help is greatly appreciated.

HI Greg,

It's possible the driver tube is bad. If you have a spare 12BY7 trying swapping the spare to see if the symptoms change. Since the IP meter indicates 60ma then we can assume the final tubes are conducting DC current.

You can download the operator and service manuals for the TS-530S at the following link:

http://w5rkl.com/kenwood-hybrid-operator-and-service-manuals/

Click on the manual link you want, the file will download in your browser. After the download completes, there are some small icons on the upper right corner, 4 of them plus 2 side by side arrows to the right that looks like this ">>". The icons I'm talking about are to the left of the arrows. Move you mouse over the icons until "download" shows up then click on that icon. This will load the manual into the Acrobate Adobe pdf file reader then all you have to do is save the manual to your hard drive. You will have to have the Adobe reader loaded onto your computer.

Once you have both operator and service manuals downloaded onto your computer then I recommend you spend some time reading them, especially the "Circuit Description" sections.

I have more manuals, TS-520, TS-820, and TS-830, plus others I plan on uploading to my website.

48452. Ham gear manuals

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-03 15:58:09 UTC
From: Mike W5RKL
Topic: 48452 Message: 48452

For those new members, and older members alike, who do not have and are looking for the operator and service manuals for their KW hybrid, I have uploaded the following KW hybrid manuals to my website:

1. TS-520 series (all 3 models) operator and service manuals
2. TS-820/TS-820S operator and service manuals
3. TS-530 operator and service manuals
4. TS-830 operator and service manuals

Included in the KW hybrid manuals are a couple of "high resolution" schematics which I highly recommend downloading and studying. You can find the manuals at the following link to my website. Once my home page comes up simply click on the link to the manual page and scroll down to find the appropriate manual you need:

www.w5rkl.com

I have additional manuals and schematics for other ham receivers, transmitters, transceivers, and test equipment I plan on uploading in the future.

Hi Terry

No 14V on the Drain of Q2 Mixer in the WWV position.

All levels the same for both Normal Channels and WWV at the RIF output. Frequencies are also correct.

Any further suggestions, please?

Many thanks

Henry de ZS6MC

From: ira parker
Topic: 48455 Message: 48455

retested as terry suggested if board conn 14 pin 1 alc input from af q31 (2.59volts) car level min and max no change in voltage. terry also mentioned that this voltage should drop to (2.0 volts) in tx it doesn't stays at 2.59?
mode cw, heaters on, sg off, 14.175mhz, meter alc

I'm assuming q2 and q7 are good from previous test. Checked voltage on q18 (0 volts d,s,g) according to schematic it should have 9.8v,0v,1.3v in rx mode am I looking at this right?

thanks,

From: <les@...>
Topic: 48456 Message: 48456

As I was fixing another issue on my TS-820s (display problem - had to put a little heat on the pins inside the DG-1), I figured I'd take a poke around and see what's inside. About the only question I can come up with on everything, the finals look to be originals - S2001, Matshuita (hope I spelled that right).

I'm not licensed yet, so I cannot transmit at all right now, so all the testing and tuning has been done into a dummy load. All the results I see from the testing look to be okay - so I would assume that the finals are just fine as well? I have no desire to change them out unless I need to. From what I have read, those tubes can last forever as long as everything has been done right over the years.

Even though you do not have a license yet...the group rules/policies still require you to sign your
post(s) with your given/Christian name. Joe-WB7UQU

Will
Just going through some old email's and came on this one. Could not help but comment. I would like to say politely that your comments are about very old technology. 3D systems used the resin and laser process but there any many other processes that make up the market today. I have mostly used the FDM (Fused Deposition Modeling) process and the parts produced easy exceed the 5,000 psi rating. They are tough durable and long lasting. While 3D modeling is not profitable in mass production is sure is valuable in limited production items. Today they are printing composite materials as well as metal parts and they are wonderful and strong. No way would I produce any gun parts from any of these printing process, but there are many long term parts made from durable printed materials. i.e. printed hearing aid shells are custom made for a single persons ear and they sure last a long time. 3D printing has long had the name Rapid Prototyping and that has been one of the main uses of the technology. Making wax investment casting patterns, and medical parts for implants etc. make the process invaluable. Oh, and long term, well the custom mount for my UHF Mobil radio is a 3D printed part and it is 20+ years old and looks and works like new.
Anyway just a few comments.... hope all is well with you.

Joe, you sir - are a genius!! I do remember reading about this as I was skimming through all the service bulletins once, but it just did not click until I read your response. Reading all the bulletins with having the radio in front of me, I was just reading stuff, with no rhyme or reason of what it all meant - just storing info for later recall.

I just took out the DG-1, removed the board with all the ICs, gave it a good squirt with some cleaner (a lot of flux disappeared then). It may have work at that point, but I figured I'd just give each pin a quick warm up with the iron. At this point, if I am on track, I figured I would have a 50/50 shot of it working right. Put it all back together and everything is great now with this lovely rig!!! I am chomping at the bit for Saturday (testing day).

Oh, BTW - the 8 - 9 jumper on the external VFO is pretty important when testing, as I found out - a little rookie mistake there, but then again, right now, a rookie is all I am.

Thanks for your help on this - your direction and the service bulletin got it all 100% for me.

Les,

Testing should be done into a dummy load, unless you have confirmed that your repairs, etc. are finished and want to get an "on the air" evaluation.

The original Matsushita 2001A tubes can indeed last a very long time. Whom ever had the rig prior to you must have taken care of it...and knew how to properly and quickly get it tuned up.
As long as your power output is within reason...nominal 100W +/- a bit...and slightly lower on 10 meters, your Ip is within specs...your HV doesn't sag below about 750 VDC or so at full output,
practice tuning up your rig(into dummy load)...so when you do get your license...making sure you have a proper antenna...etc...hit the air waves!

also, thanks for you update on identification

Les,

Thanks for your compliment but, I am far from a genius...just have been there and done that,
along with many other hams that had, or still have an 820S.
Also, as you found out...that jumper plug (or suitable piece of wire) is important.

Ira

I am very busy with rigs coming out of the woodwork here! I think I told you that the ALC voltage at the output of the Audio board should be where you set RF-1 level which should be approx 3.2vdc. You can accurately set that with your DMM because RF-1 is a low Z power supply and the impedance (load) of your meter wont pull it down as you measure it.

The ALC bus is a High Z power supply and just about any meter you place on it to measure it will pull it down. So I am guessing that the 2.59vdc that you measure leaving the Audio board and arriving at the IF board is at 2.59vdc instead of 3.2vdc due to the impedance of your DMM pulling it down. If you measure ALC at Conn 14 Pin 1 in receive mode you should be seeing 2.59vdc or whatever it is you are reading at Audio board.

As I previously explained you must have sufficient RF drive level at 6146 control grids and proper dc operating bias voltage inorder to have approx 45 ua grid current flow. When this small grid current flows Q31 ALC amp (that you replaced) will pull the 3.2vdc down about 0.5vdc to 1.0vdc. So you could expect to see anywhere from approx 2.0vdc to 2.5vdc at Conn 14 Pin 1 in transmit mode. Again for this to occur you need approx 45 rf volts at the 6146 control grids and approx -60vdc bias.

I believe you said you also replaced RL-1 so your TIF amp should be seeing the necessary ALC bus voltage to produce RF drive output in Tx mode as the relay switches from AGC bus to ALC bus. However, you should measure Gate 2 of Q2 to validate this.

I think it may be best if you restate your problem and what you have done so Mike or others can run with this. Suggest something like:

"On my TS530S I have no ALC indication when I try to load the rig in Tune or CW modes. It previously worked fine and I am experienced at loading this rig. I also have no RF output power as indicated by no meter indication in the RF position or on my external wattmeter. I have replaced ALC amp transistor Q31 and RL-1 relay. I have measured and adjusted RF-1 to 3.2vdc. I have verified that I have 2.59vdc at the ALC output on the Audio board Conn 9 Pin 1 and I have confirmed that I have the same 2.59vdc at the IF board at Conn 14 Pin 1. I have not measured the RF drive at the TIF output on the IF board and I have not measured the RF drive at the control grids of the 6146 final tubes. This is because I have no test equipment to measure RF drive levels. I did measure the bias voltage on the 6146 control grids and it is approx -100 in Rx mode and approx -60vdc in Tx mode. The radio works fine in Rx mode which tells me that Q2 mosfet (TIF amp) is good. I have not measured Q2 Gate 2 in Tx mode as I assume the ALC bus voltage is available from the new RL-1 relay I installed"

A statement similar to this will help Mike or Dave or others to help you run from here.

I must get back to work so wont respond anymore. Good luck.

48463. Re: TS-520 S S-Meter deflects full scale and stays there, when set to receive WWV

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-03 22:18:08 UTC
From: <wagstw46@...>
Topic: 48447 Message: 48463

You mention that the AGC line is at 1.2 vdc in WWV position. I assume that 1.2vdc is for OFF, FAST, and SLOW? Is that correct?

You said that RIF level was normal and same on the ham bands as on the WWV position. I dont see in my notes what the level would be for a TS520, but do have a level noted for a TS830 and with signal generator supplying signal at SO-239 to drive the S meter to full scale deflection I show a RIF signal level of approx 30mv rms.

So to measure the RIF signal you should drive the rig on one of the ham bands until you get full scale s-meter indication and then measure the resulting RIF level with O-scope or RF millivolt meter. Then remove sig gen and switch to WWV and measure the RIF signal.

You could also try adjusting T4 and T5 to reduce the output of Q4 and see if that changes anything.

Several to choose from at Mouser. I think the
ones you are referring to are all tubular. I used
these to repair my Heath SB-610 scope and they
were smaller than the originals that I replaced.

I would use 3kv or more for all of them.

Re: Inexpensive Digital RF MV meter EBay item 281216433787 ex-China
Terry,
Did you have any problems with the Chinese supplier (t-mall2013/bluelect)? I ordered one of these and I'm still waiting after 2 weeks even though he has been paid by PayPal. I had to deal with him direct thru PayPal as he insisted on by-passing EBay. A bit naughty. Couldn't get him to use EBay so I could see my "purchase history" and order details as well as a tracking number. After repeated emails, he has gone completely AWOL. Do you have a direct email address for him? I might be barking up the wrong tree there but hope you can shed some light on the matter. Thanks

Thanks for the complements. I have been involved in this
technology for a long time but now enjoy retirement. If we (and I
mean we because I need a connection as to what the folks want) are to
pursue this project I need information. Terry K9TW was the lead for me
on the Kenwood sprocket project. He had spare parts, shafts, sprockets
etc. that he sent me to copy. I sent the parts back to him after I
copied the dimensions. So, I think *we* could start down the road and
see what the project entails. First it would be good to get a picture
of the parts in the radio's, identify which radios, and then follow with
an identification. Then if it looks doable, get the parts to copy and
make prototype parts and have someone install them and check them out.
Then I can put up a WEB site and we can be on to helping our hobby. I
need to emphasize, I know there is a little money to be made but I am
not into this as a business venture I am in it to help other Ham's that
need some hard to get parts and of course to have a little fun making
something of value. More about me and my personal interests later.
I also have some information that there is a need for Heathkit
Transciver parts similar to the parts that I have produced. We'll see
in the future what that need is .

So, keep me posted and tell me what you think.

Mark

I think I used NTE638 TV damper diodes and NTE525 fast recovery diodes?

I dont see many of these so not a lot of experience, but have seen blown caps and diodes. Caps probably took the diodes. I think good idea to just replace all the PIO with mylar. I would not want to use a standard 1000piv diode in this service. I dont know about the Heath monitor scopes, but I believe the SM-220 has voltages in the 1300 to 1400vdc range? I dont have very good notes, but I see a note about a BY228-3 damper diode. My guess all obsolete now. Have also seen couple of Yaesu scopes but many moons ago.

Hope to check in tomorrow to get an audio check on customers rig if propagation will cooperate. Made a couple of contacts but trust your ear.

Bill,

These are PIO and the muck that has come out is not good for your health. Make sure you use gloves to clean up. Have a look on ?bay, there are some 0.1uf PIO, NOS. I have purchased from this sellar and he is great to deal with. I have installed in 2 of my SM220 and makes a huge difference. If you have any problems finding let me know off list and I'll pull up his details

Subject: [TS-520_820_530_830] Source for HV Caps

Folks
I bought an SM-220 to go with my TS-830S and have found that the caps have died and spilled their guts all over the pc board. These are 0.1uf @ 1kv and 2kv.
Anyone know of a source for them? No luck at Mouser or DigiKey or Antique Radio.

Thanks,
Bill

Thank, I appreciate the heads up on the caps.

I spoke to a good friend who knows more about caps than anyone in the world (he does it professionally for un-named agencies) and he said they were polyproplyene Film caps, not electrolytic caps as I had thought. I should have looked more closely at the schematic, I'll check on e-bay for them. I found the couplings on e-bay and they should be here Monday. Wonderful place, e-bay :-)

Any other hints about the SM-220? What about the HV diodes?

Hello Mike,

I received the new 12BY7 and installed it in my radio but I still have the same problem, I am still trying to figure this out it has to be something simple
as I have not changed anything on my radio, any suggestions would be helpful. Thanks for the help and information you have already giving to me.

Les,

Congrats on your "General" ticket!! You have now opened up a whole new world. You do need to explain to your YL/ XYL, or significant other, that you now have lots of other stuff to do, and will not have the time to mow the lawn, take out garbage....and other mundane tasks that afflict non-hams....A bit late for "April Fools Day".....hihi

Again, Congrats! Hope you stick around here and enjoy participating in keeping these older rigs working for many years to come.

Bill,

I have never seen the HV diodes go open circuit, nor have I seen the cap get to that stage. But saying that I usually change caps when the trace starts to fade out. You can lift one leg of the diode and check to see if they are open circuit. If they are then they will need to be replaced. Dont forget there are 0.1uF 1KV and 0.1uF 2KV caps in that part of the circuit, make sure you replace all the HV caps.

What couplings are you refering to?

Please discharge the HV caps and the Driver tube plate 300 volt supply caps as I have found in 3 rigs now that the bleeder resistor R9 in the 530s and 830s to be open and look like new. Do not trust R9 bleeder to do it. I don’t know if it could kill you, but a very nasty shock and unpleasant surprise that could result in cuts and/or damage to the rig.

Best thing to do is discharge with known good alligator jumper clip lead with 2k current limiting resistor and then measure with known good voltmeter before bare hand touching. I have a couple of jumpers made from test probe wire with a 5 watt 2k resistor in series.

I always clip my ground jumper on directly at the HV filter caps and leave in place for a while and never discharge with a screw driver at top of plate choke. Do the same to the 300 volt supply. I do not short the plate choke to ground as I have no idea if the main and small VHF choke windings have continuity and no sense dumping a lot of joules thru them needlessly.

There is a capacitor phenomenon called "dielectric relaxation". You can touch your screw driver or ground lead the cap and get the spark and pop and think you have discharged it. If you wait a few seconds and measure the cap you will still find pretty significant voltage on it. It’s a very good way to get a nasty shock.

Dayton Hamvention Kenwood Legacy Forum:
This year will be the first year for the Kenwood
Hybrid Legacy Forum to be held at the Dayton
Hamvention. The forum will be Sunday May 18th.,
room #2, 10:30 □ 11:30. The following preliminary agenda has been proposed:
History of the legacy products.
* Resource help with parts, documentation, etc..
* SDR integration into the legacy line.
* Rewinding a TS-830 L41 coil.
* Tips & Hints.
* Questions and Answer Technical Session
We hope to see you there.

```
Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

```
We had 20 stations checking in under good band
conditions. There were 6 new stations checking
in, KC8IMB, KK4RF, KC8SBZ, VA3DPR, N3FTL and N3JAH.

We had the following number of radios checking in.

4 running TS-520(x)
4 running TS-530(x)
2 running TS-820(x)
2 running TS-830S

I was running my TS-940s, Drake L4B amplifier.

The Sunday 20 meter net we had 19 check-in under
fair band conditions. There was 7 new check-in,
W4KRK, WT0V, KD0MZL, K0QND, NM0V, KB4DBR, and
KD0VVH. We had the following number of radios.

3 running TS-520(x)
0 running TS-530(x)
```

2 running TS-820(x)
3 running TS-830S
3 running TS-440S (Not a hybrid, but old enough to make it one)

I was running my TS-820 twins.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 82, Sunday□s total = 73
April 2014, Saturday□s net total = 22, Sunday□s total =19 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Yes I had to bite my tongue when I recently saw pictures of screwdriver shorting top of the RF plate choke to the PA cage being touted as good practice.

I said nothing as I know it is common practice and taught by many well intentioned hams of all ages. It simply is not good practice.

My KW Hybrid and my customers are not welding machines. Any time you see that pop and sparks you have just discharged a huge amount of power in a very very short period of time. Why would you see sparks? It is molten metal that is flying in the air. Not likely could fly into your eyes but it is possible. Besides that I dont want any burns, arcs, pits or transfer of any metal on my PA cage.

As Bill says you are relying on the continuity of the small VHF choke and the main RF plate choke windings with this method and if you get no spark you could be fooled into thinking there is no voltage and get a nasty surprise.

Think about this and do some simple calcs. This is science and not voodoo. A 60uf cap charged to 900vdc has 24 joules of stored energy. That is a very large amount of energey. If you discharge that in 1 millisecond you just asked your HV lead wires, plate chokes windings, PA cage metal and of course the capacitors themselves to dissipate 24,000 watts! If you slow it down to 10 milliseconds now at 2400 watts, and slow it down to 100 milliseconds now at 240 watts. The entire series string would much rather see 240 watts than 24,000 watts.

A good alligator test lead jumper with a series 2K ohm resistor will discharge the 900vdc to approx 37% (1 time constant) in approx 120 milliseconds.

Of course you still need to perform a contact voltmeter test before barehand touching as Bill points out is the standard good practice that assures you dont get shocked. No electrician gets killed or burned who religiously measures the point they want to touch with a known good voltmeter. Those who get killed, lose a limb, lose eye sight, or get severely burned are those who take short cuts and touch something that they thought was dead.

Dont forget what Bill says about "dielectric relaxation" this is why high voltage caps are stored with the terminals shorted. Those of us who worked in TV repair know about this effect. I think you may be able to find a You Tube video or two that demonstrates shorting a cap and then connecting DMM and watch the voltage build back up.

Just dont trust those bleeder resistors and use proper discharge tools and techniques and always measure to ensure no voltage on the HV and 300 electrolytic caps.

Thanks to Bill for this spot on counsel.

Terry K9TW

Thanks for the responses! This radio has been the subject of questions posed by Chad a month or so ago. I'm not sure how to reference that conversation here, but I can give it a try if need be. It has been hacked for CB, but the lower bands appear to be untouched. I am trying to focus on the receiver issues before worrying about transmit. The S-meter had pegged on him upon power up and he hadn't gotten past that when I volunteered to have a look. I am REALLY trying to gain a better understanding of how these work and how to read the schematics. Both VR2 and VR3 were broken on the AVR board which have been replaced. This brought the S-meter back to reality and also returned the missing volume. The current problem I'm working is that the receiver seems to have low sensitivity. I tried to peak the S-meter using the drive on each band, but I get pretty much no deflection at that point. WWV works great and reflects well on the S-meter. In normal receive I can bring in some strong signals but it's clearly very light with little meter deflection. The voltages on the AVR board are good in response to a suggestion by Terry in the other conversation. WWV switch is good. My theory in looking at the block diagram is that if WWV is good while normal receive is not then I could assume that the issue lies between the antenna and the BPF where both signals come to a common point. Does it make sense to focus there?
Thanks again,
Charlie - AC6ZX

Charlie:

There is no BPF between the Antenna and the Ant Coil unit. There are two resonant wave traps L11 and L5 one series and one parallel to block and suck out your own receiver IF signal from the front end and there is a 4:1 step up transformer L1. Not often that L1 is bad, but it could be. If it is bad signals will be way down.

You can test that by signal injection at NAT and at RFG. If no RF sig gen then just touch center conductor of antenna coax feedline PL-259 to RFG. If good copy then likely L1 is hurt. If still no copy by injecting at RFG then might have bad Q5 rf amp or bad bias voltage or bad AGC voltage to it.

The front end uses two different RF amps. WWV uses Q9 JFET and the ham bands uses Q5 dual gate mosfet. Q5 is in a socket and you could pull Q3 TX mixer and try it in the Q5 socket. Do that with rig powered down so you dont damage the mosfets. Can just leave Q3 socket empty for this test. Not likely that Q5 is bad, but may have taken a hit of nearby lightning.

Between the So-239 connector to the NAT terminal (some rf boards it will be labeled as HAT) is the Ant relay NC contact and the JJY switch contacts. I have had a broken wire on the JJY switch.

Terry K9TW

48496. Re: [TS-520_820_530_830] Re: TS-820S: no power output but power burst on first PTT action

From: Jose V. Gavila
Topic: 48301 Message: 48496

Hello Terry and all the Group,

Well, I got the TA7201P replacement and now the audio output is nice and constant :-)!!!

So I have got back to the original problem: no power output but with a very short power surge when first pressing PTT on CW mode, and similar but lot less powerful when on TUNE mode.

I have even tried a working IF UNIT from another rig... but it keeps doing the same.

Summing up, if I inject a low level signal on the RF UNIT (a 30mV signal on RF UNIT TIF input), I get about 50W output, so it seems that the problem is on IF unit, where TIF is generated. But, having checked a replacement unit, and with a very similar result, I am a bit lost now.

Any hint?

Thanks!

JOSE

Hi,

Remember to remove any rings, watches, etc when you are working on the internals in the radio.
Shorting the HV with a screwdriver can cause the metal from the screwdriver to splatter at you and cause an eye or other injury.

Hi Jose:

Well clearly not getting TIFsignal from either of the IF boards so you have to ask yourself what does Q1 TIF amp dual gate mosfet need to produce output that it gets external to the IF board and what is most common failure?

1. Need 14vdc Drain supply from Conn IF-1
2. Need 9vdc bias voltage for Gate 1 from Conn IF-1
3. Need dc control voltage for Gate 2. That control voltage is the ALC bus voltage from Conn IF-3 AGL. It is provided by switching the Aux relay contacts from AGC to ALC. I know you said you cleaned the contacts and I think swapped with the Ant relay, but in my experience loss of the ALC voltage to the TIF amp is most common failure. I assume you have a DC bench supply so you can use it or a couple of 1.5vdc batteries and apply +3vdc to the AGL terminal on the IF board. OK to just parallel it up and see if that gets Q1 turned on.
4. The Balanced Modulator needs Carrier Osc and it gets it from Conn IF-5 CA2.
5. The Balanced Modulator needs dc bias for the ring diodes from the CAR Level Pot (can measure at TP-2). It gets this voltage from Conn IF-5 CV pin.

Can put O-scope on TIF output at Conn IF-3 and see the momentary shot of output. Normal level is approx 100mv P-P.

Jose:

I forgot to mention you also need ALC control voltage at Conn IF-5 on the ALC pin to provide dc control voltage to Q18 so that you have DSBSC output from the Balanced Mod. This voltage comes directly from the RF board and is not switched by the Aux relay on the Relay Unit board. Of course if you have no 3vdc on that ALC line coming from the RF board then will have no AGL voltage to the TIF amp even if you do have a good relay contact. So you might want to measure ALC voltage at RF board at Conn RF-3. If you have no ALC voltage at RF-3 then make sure you have 3.3vdc RF-1 at RF-3.

I removed the RF board to look for problems on the foil side of the board, what I found was R36 and R37 are open. R36 is a 100k 1/2w and R37 is 3.3K 1W does anybody have an idea what I did to cause this to happen? I want to replace these but I am not sure of the type resistor the R36 is,I thought maybe a carbon, the information in the service manual just says solid 100k 1/2w.

Thanks

Greg

You didnt do anything.

These are the screen grid voltage divider resistors for the 12BY7A driver tube. I have two pristine looking R36 100k resistors here that are both open.

In last couple of months I am starting to find open carbon resistors and I sure hope this is not a sign of things to come. Just replace both of them with Metal Film.

When done measure the screen grid voltage. Do that to make sure someone hasnt messed with 300 and 210 to increase the screen grid voltage. Not likely but good to see if you have proper screen grid voltage on Pin 8 of the driver tube. If you leave enough lead when you bend R37 over you can measure voltage on the lead loop and it should be approx 247vdc.

Can measure 210A supply at Conn 9 and should be approx 256vdc in Rx mode. If you measure approx 339vdc you know someone has performed a QRO mod and you will want to undue that. Again not likely but I would check.

While you have the RF board out do a good visual inspection on the soldering at the Driver tube socket lugs and all three of the Drive air variable capacitors. Put a tube in the socket and press and wiggle it as you watch the lugs. Grasp VC-1, VC-2 and VC-3 frames and wiggle/press and watch the soldering at the heavy lugs. Common place for cracks which cause intermittents.

I have about 3.2Vdc on that pin.

> 4. The Balanced Modulator needs Carrier Osc and it gets it from Conn

There is a 1Vpp signal, both on RX and TX

> 5. The Balanced Modulator needs dc bias for the ring diodes from the CAR

> pin.

Yes, that is also working fine.

> Can put O-scope on TIF output at Conn IF-3 and see the momentary shot of
> output. Normal level is approx 100mv P-P.

I see the momentary shot on TIF signal. With the LP-100A, on CW mode, I get power peaks of 150+ Watts. But then continous power is just around

2W. I have cheched and it is even lower on SSB (close to 0.3W peak)

Regarding your last message:

> I forgot to mention you also need ALC control voltage at Conn IF-5 on
> the ALC pin to provide dc control voltage to Q18 so that you have

Unfortunately, that signal is also OK, both at RF and at IF boards.

I am really puzzled with this repair... There should be some TX gain related problem, but the ALC seems to work OK.

I think one test I could do is to get my TS-820 out of its storage, and pick up the RF board, to replace the one on the non working rig, just in case it makes any difference and can give some other clue.

Best regards and thanks a lot for your help!

You said you have 3.2vdc at AGL on the IF board at IF-3 Pin 6. I assume that is with rig flipped to send in CW mode? Must measure it in TX mode. Your meter should pull it down perhaps to as low as approx 2.6vdc.

Best place to measure the required DC and signal voltages is at the leads of Q1 dual gate mosfet. Typically if have them at the Molex connectors should have them at the active device where they are needed. Not always the case with a TS530 or TS830 with the smaller molex connectors where can have bad pin soldering or broken trace to pads. Not common on the TS-820 rigs and besides you tried two different boards.

If you have Q1 drain, gate 1 bias, gate 1 rf signal from xtal filter, and gate 2 alc you should see RF output at TIF IF-3 Pin 2. Not a pulse of RF but approx 0.038mv rms of 8.830 mhz rf drive with rig flipped to send and CAR Level Pot advanced. On scope TIF will be not be clean stable sine wave as the VCO oscillator leaks back from the RF board so you will see harmonic rich TIF signal unless you have low pass filter capability on your O-scope. Must use a 10x low capacitance probe to measure it.

This has to be something very simple we are overlooking.

You are able to get RF output when you sub the TIF input signal to the TX Mixer on RF board.

So assuming you have good TIF output at the IF board the problem has to be between IF board Conn IF-3 and RF board Conn RF-1 Pin 10. Not typical to have bad wiring harness. Try jumpering from TIF at IF board to TIF at RF board.

I dont think much more that I can do to help you. Just go back to Q1 and make sure you have what you need on the Drain, Gate 1 and Gate 2. By the way the signal level at the output of the xtal filters can be measured at cathodes of D6 and D8 and it will be low. Approx 20 to 25mv. At the input at cathode of D7 you will see approx 50mv. I would say minimum input will be approx 25mv and minimum output would be approx 19mv.

Maybe the Filter switching diodes are not getting their needed bias turn on voltage? Suggest you measure the RF drive level at input and output of the xtal filters. If have input and no output then need to measure the bias voltages on the switching diodes.

You can place a jumper with a .047uf cap across the filter and if you get TIF output you know the filter didoes arent being turned on in TX mode. You can start by reading the voltages at IF-2 Conn, but I would also read them at the diodes. D7 anode = 2.98vdc D7 cathode = 2.34vdc and D8 anode = 10.0vdc D8 cathode = 9.4vdc.

If you have good filter switching voltage to the diodes then should have RF input signal to Q1 Gate 1. Not likely you would have two bad xtal filters on two different IF boards.

That is best I can do.

Hello Terry,

Thanks a lot for taking so much time to help me. I will carefully check all of this and will get back with the results.

Now I have another semi-working TS-820 side-by-side with the faulty unit, so I can compare signals in real time. I define it as 'semi-working' as it needs some alignment and perhaps some repairs also. But it generates about 70W, which is good enough to compare measurements with the other unit.

I have a well equipped lab, with plenty of test equipment, and about 25 years of radio and electronics repair experience. But this one is clearly overwhelming me at the moment.

BUT I am not easy to defeat ;-) and, with your help, I am sure we will finally find the bug!

Thanks and best regards,

JOSE

Jose:

Yes I think I have seen pictures of your RF lab. My bench is much more modest, but very adequate for KW hybrid repair and alignment. What little I make servicing them I usually spend to upgrade test gear. Last year put back enough to purchase and erect Rohn 45G tower and Mosley Tri-band yagi and rotator.

I am sure you will find the problem. I would have bet on no ALC rail voltage at IF-3 AGL terminal due to bad relay contact. Most common problem with an easy fix.

If I were you I think I would jumper across the SSB xtal filter with a .047 cap (value not critical) and if rig comes alive you know you have bad switching diodes or not getting the forward bias from Conn IF-2 Plug. If you dont have a CW filter and the Plug is in either B or C positions you wont turn on the path thru the SSB filter in Tune or CW modes. You could also test this by placing rig in LSB/USB and turning up mic gain and whistling in the mic with mic gain advanced.

Was the rig working and just quit or is this rig new to you and comes with the problem?

What filters do you have installed? Is the IF-2 Plug in the "A" position. If you have only the SSB filter make sure plug is in the "A" position.

Greetings Group!

I want to state my support for Mike's(w5rkl)statement, regarding "personal" disputes regarding members of this group. Be it hereby stated:

IF, you have a personal beef/problem with another member, keep it between the parties involved...ie; direct email contact...which every member can find another party's email address...or other communication venues...NOT ON THIS BOARD!

The ONLY possible exception might be; alerting the group of a "scam," Which I have done in the past. This will require a complete statement of facts. If you are deemed to have manufactured a "scam" story to get back at another member...because this person said something to hurt your feelings...your membership/participation in this group will be terminated. If, for some reason you can not abide by the rules/policies, PLEASE feel free to "unsubscribe" now, or the other "Moderators/Co-owners" can do it for you.

We try and provide a environment free of QRM/QRN and other "stuff," so we all can focus on the primary reason for this groups existence.

The continuing difficulty over the recent past surprises me. Some very colorful language and, physically impossible acts have been directed at/to the "management." These are NOT the people this group will tolerate.

So....stop running with scissors...work and play well with others....

we now return to our regular program.....

Not long ago, I shipped my mildly ill TS-830S to Terry, K9TW, for a healing visit employing test gear brand/model expertise I do not possess. The radio returned today, happily, in fine fettle and performing better than it has since I adopted it a year or so ago.

I will not detail the repairs Terry made but will attempt to impress you with the levels of inspection, troubleshooting and post-service testing undertaken. It is all documented in a thoroughly prepared service report. After a initial review of expected service,the first section of the 16-page document comprises observations made upon initial visual inspection of the unit. Here, we read of Terry's discovery of such minutiae as a stripped chassis screw hole and a light dust buildup on the PA cage fan blades. But, we also learn of many loose internal screws and an incorrect cable dressing which could, in time, turn troublesome. We are also informed of sloppy interaction among chain-driven variable capacitors VC1, VC2 and VC3 and the reasons for this anomaly. Terry, with Holmesian powers of observation, also detected what scattered components I had replaced in my restoration attempts.

The juicy bit of the report, of course, was Terry's chronicling of the repairs made, the full factory alignment procedure, post-service testing and recommendations for further owner action. The last few pages of the report are devoted to frequency response charts based upon audio and variable bandpass tuning (VBT) measurements. In all, Terry's report was instructive, useful and even entertaining. Above all, it demonstrated the care and pride that Terry takes in his expert work. In all my years in hamdom, I have never been the benefactor of service and documentation as thorough and of such high quality as K9TW's.

Thank you, Terry! I recommend your service to all highly and without reservation.

VY 73,

Craig
W3CRR

Craig

I certainly appreciate your kind endorsement, but you have only had time to drive it around the block. You might want to take a road trip or two before passing judgement!

As to the final report you cite I generally reserve that document for "special customers". Now others will expect the same thing. Thanks to you I will now have to raise my rates!

Just remember we are dealing with 35 to 40 year old radios here and anything can go wrong at anytime. Hopefully yours will give you many hours of enjoyment.

Thanks again and enjoy.

Terry K9TW

Just a few thoughts.

There could be activity taking place through private emails. Also, it's possible that members may be studying reference material to get a better idea of what's happening in the circuit they are trying to troubleshoot.

Bingo! The center conductor to HAT (the NAT reference was driving me nuts... thanks for clarifying) produced the long awaited activity. L1 appears to have cracks on the edges of the adjusting point (please forgive the horrific terminology). Can you tell me if or where this part might be available? Thanks as always, Charlie - AC6ZX

Thanks all, just havent seen too much over the last few weeks and absolutely nothing yesterday apart from my test message. This happened last year aswell, then got a huge dump and was several weeks out of date. No harm and No foul.

Yes I know what you mean Mike, my XYL found a great 1960s understanding receivers and tube book, so have had my nose in it for weeks. Very interesting in getting a better understanding. Now if I could only find a book on 400Hz basic power supplies

I guess it's the onset of getting older, but last winter I was bit by the Kenwood bug again. Perhaps a bit of reliving my youth, partly a rekindled love of yesterday's technology. And since next month I will celebrate my 43rd year of ham radio I decided to build a Kenwood station again.

I have been acquiring parts to rehabilitate my new to me TS-530S. Among them were the all important shaft couplers. I ordered some from a well known vender, they seemed fine but large. When perusing K4EAA's website I noticed his. Sweet, so I ordered some, a replacement RL1, and other stuff. They came in 2 envelopes while I was off on a business trip. Got home on Friday and they were sitting on the table. Wake up on Saturday and saw only 1 envelope. The XYL cleaned the table and accidentally tossed them and took the garbage out. No biggie, I'm not a dumpster diver so I decided to order more, and a couple of 12BY7A tubes.

They came while I was away on another business trip, but when I got home I put the tubes on the tester and one was a dud, no filiments. A quick note to Ken had a response within minutes (!) and he offered to send me a replacement the next day. I sat dumbfounded for a minute and realized I needed to buy something else from him so I would cover the cost of shipping. Unfortunately USPS didn't deliver last Saturday, and early Monday I was on another airplane. They arrived Monday, and when I got home today put them on the 707 and they tested solid.

In my 43 years I have been shafted at hamfests, print want ads, electronic want ads and of course eBay. To have had dealings with a true gentleman has renewed my faith in my fellow hams. Ken is a real stand up guy. I couldn't be happier.

Now to see if a I can fit the time in to replace the driver and replace the bandswitch coupler between the honey-do list and other obligations before catching yet another plane Sunday morning.

73,
Joe N9JR

Joe:

I cant imagine Ken charging you shipping to send you a replacement 12BY7A tube?

I dont know a single person who has had an issue with Ken.

I once bought a pack of brass couplers and it took some months before I went thru them all and one of them in the pack would not fit on the shaft even after backing out the set screws completely. I tried it on more than one shaft. I had no way to measure the bore id, but clearly it was too small. Dont understand how that could happen unless it somehow missed the final pass in his CNC lathe? Anyway, I contacted Ken and next day he sent me 2 couplers for my troubles and no shipping charge.

About 90% of the time his wife Barb fills the orders. I dont know anything about her technical back ground but I do know she understands old fashioned customer service.

I still buy parts from Ken that I could get at lower price by buying in bulk. I do that because of the contribution he has and continues to make to the KW hybrid community. There are people who believe that "knowledge is power". Ken isnt one of those. He has freely shared all of his vast intellectual property and over 10 years of hands on experience.

Now if we could talk him into serving as a coach/mentor on this reflector!

Terry,

I may not have been as clear as I might have been, but Ken offered to send a replacement for the duff tube the next day. I was so taken by his instant response and kind offer I felt the need to order something else so I would pay the shipping. Sort of meeting him in the middle.

For what it's worth I ordered another 12BY7 and he sent me 2 Sylvania tubes. Useful in my Kenwood and more so in my Drakes.

Indeed, his site is a wealth of information. I'm currently reading a book by David Maranis titled "When Pirde Still Mattered: The Life of Vince Lombardi". And for Ken K4EAA pride still does matter. I just wanted to share my outstanding customer service experience.

Regards,
Joe N9JR

All,
I have had very great luck ordering from Ken. He has always shipped within 3 - 4 days I have had my items.
I did have one coupler that would not go on the shaft. I took my pocket knife and placed it in the hole and turned it a couple of times. A small burr was removed and all was well.

Paw Paw:

I am not senile yet and have more than a modicum of mechanical ability.

There was no burr in my brass coupler. Neither end would go on and it was clearly a smaller ID. I have a drill press and hobby lathe and thought about opening it up, but decided to send back to Ken in case it was not just a one off. He did autopsy on it and could not determine how it got past his QC inspectors. Not sure how many inspectors on his payroll. Apparently only doing random sampling? I doubt he had the heart to fire any of them.

I suppose could have tried a rat tail file or pocket knife.

Terry: Regarding the 2K resistors recommended for discharging HV capacitors - what do you recommend for minimum rated watts, and does type of resistor matter at all.. (carbon, film, wire wound)? I have to admit....in my past tube work Ham and Audio, I used the screw driver straight from the capacitor lug or wire..to ground...repeated untl meter showed close to zero volts...

Thanks,

Bob / WA2JAJ

Topic: 48529 Message: 48529

I have an 830S with low power out on 12 meters.
All the other bands are fine, putting out 100W plus on 160 through15 meters, 90 on 10 meters, and only 50W on 12 meters. I have peaked the Drive, RF, and Antenna slugs on the RF board , and used Deoxit on the band switches for no help. The rig operates perfectly in all other respects.
All readings were taken key down with a Bird 43 watt meter.
I am kind of scratching my head on this, and any help would be welcome
Thanks,
David

Bob:

Many people have employed the screw driver for years and dont always apply it for long time or multiple times and dont perform a contact voltage measurement after the initial fireworks. They are unaware of "dielectric relaxation" phenomenon. That includes me in my youth. I am sure there are burn marks on my 1960s vintage transmitter pa cages and screwdrivers.

It is your rig and up to you. I just always try to present good practice and the basis for that practice. Most of the time if you wait long enough the bleeders will do their job, but do you want to bet your life on them?

Also the habits and practices that you employ with a 100 watt transmitter almost always will just carry over to how you would work on a 1000 watt transmitter where you have power supply voltages that are 3 to 4 times or more higher.

I would use a 5 watt to 10 watt resistor. It can be any type. Key is dont want one that will open circuit over time. So to me that would rule out carbon. It is hard to calculate the wattage and you cannot simply use Wattage = V squared/R because of the RC time constants involved. The duty cycle is very short so a pretty low wattage resistor can safely dissipate pretty high pulse current. With 60uf and a 2K bleeder looking at approx 120 millisec for 1RC and approx 600 millisec for 5RC. So a 2 watt or 5 watt resistor should not fail in this service. Just to be safe I use a 5 watt in my grounding jumper.

We probably need our MS EE members in here to help us with specing the resistor. I have seen some rules of thumb for sizing the ohmic value as well with 5 ohms per volt being mentioned. This would see us employ a 4.7k ohm resistor. I have seen some fellas recommend a 10k resistor. I would not go that high. I have had good luck using a 2.2k ohm 5 watt resistor. Of course if go to high then takes too long to discharge and too low the current stresses the capacitors and plate choke windings if people persist in grounding at that location.

Sorry cant be more precise.

Terry K9TW

David

A O-scope, RF millivolt meter, or RF probe (multi diode) and VTVM will tell you in a matter of minutes. A Heath IM-18 and PK-3 is a good combo or any similar unit. These old units work well as wont load down the tuned circuits. May have to peak the Drive control to restore max output power on the wattmeter after touching the probe tip to the point where you want to measure the RF drive voltage.

The TX Level Diagram is on page 44 of the 3rd edition service manual.

Load up on 100 watts output on 14.2 mhz and record your RF drive levels for reference. Then load up to as much as you can on 24.930mhz.

Measure the RF drive level at the control grids (pin 5) of your 6146 finals. You should see approx 40 rms rf volts at 100 watts output. If low then work your way back to the TX Mixer. Go to Driver tube plate, driver tube control grid, and output of the TX mixer. Where the RF voltage is low is your problem.

You measure the rf voltage level at output of the TX Mixer on the RF board at TP-4. At 100 watts output you should measure approx 2.8 rms rf volts. At 50 watts output should see something like approx 2.0 rms rf volts. This is the RF drive level to the control grids of your Driver tube.

Typical problem is loose bandswitch rivet on the Drive deck so that the parallel resonant circuit is not being switched in or is being switched in with high resistance.

David:

I forgot to mention that after you load up to 100 watts output on 20 meters flip the SG switch off to take your TX Level Diagram reference readings. All you need is rf drive and operating bias on the 6146 control grids. No reason to stress the final tubes while taking these drive level readings.

Same with 24.930. Load up to 50 watts out and then flip the SG switch off to take the rf drive levels.

After loading to 100 watts output and turning off the SG switch should see something like 46 rf volts at 6146 control grids. After loading to 50 watts output and turning off the SG switch should see something like 34 rf volts at control grids.

David:

None that I am aware of. Actually not too bad a process to solder the rivets or place small jumper wires if it is on the deck nearest the PA cage front wall. Of course have to remove the RV board.

I would not jump to conclusion it is loose rivet just yet. However, when you have low RF output on one band it is almost always bandswitch related. You can try applying deoxit in place. I dont spray it on. You are really more spraying at than spraying on the contacts. Be careful poking around the contacts because easy to bend the fingers and wreck the switch.

I turn the bandswitch to get the wiper up at approx 1130 to 1200 position. That will be with bandswith at 1.5. Then I use an artist brush to apply a drop of full strength D100L (absent that just use D5) to the wiper and then rotate bandswitch multiple times back and forth thru complete rotation to distribute it to all the contacts. I bring the wiper back up again and apply another drop and repeat rotation again. I try to get the drop to work on both sides of the wiper. Very easy to see the wiper if you look over VC-3 from the side of the rig. You want to do this on S7, S6, S5 and S4. Just bring wiper up to top and apply the deoxit and then distribute it via back and forth rotation and repeat this a couple of times.Sometimes this will work. Do it down powered as there is 300vdc plus on S7.

Dayton Hamvention Kenwood Legacy Forum:
This year will be the first year for the Kenwood
Hybrid Legacy Forum to be held at the Dayton
Hamvention. The forum will be Sunday May 18th.,
room #2, 10:30 □ 11:30. The following preliminary agenda has been proposed:

```
* History of the legacy products.
* Resource help with parts, documentation, etc..
* SDR integration into the legacy line.
* Rewinding a TS-830 L41 coil.
* Tips & Hints.
* Questions and Answer Technical Session
We hope to see you there.
```

```
Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net
```

```
Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

```
Jimmy, WB2KNR ran the Saturday net. He had 13
stations checking in under very poor band
conditions. There were 6 new stations checking
in, KC8IMB, KK4RF, KC8SBZ, VA3DPR, N3FTL and N3JAH.
```

```
We had the following number of radios checking in.
```

```
3 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
0 running TS-830S
```

```
He was running his TS-520.
```

```
The Sunday 20 meter net we had 14 check-in under
poor band conditions. There was 4 new check-in,
W7JJH, KD0FDS, N6ZZO, KG7KME and VE5HKC We had the following number of radios.
```

5 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
3 running TS-830S

I was running my TS-820 twins.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 82, Sunday□s total = 73
April 2014, Saturday□s net total = 35, Sunday□s total =33 (Month to date)

Net Info:

HI Greg,

It's possible the driver tube is bad. If you have a spare 12BY7 trying swapping the spare to see if the symptoms change. Since the IP meter indicates 60ma then we can assume the final tubes are conducting DC current.

You can download the operator and service manuals for the TS-530S at the following link:

http://w5rkl.com/kenwood-hybrid-operator-and-service-manuals/

Click on the manual link you want, the file will download in your browser. After the download completes, there are some small icons on the upper right corner, 4 of them plus 2 side by side arrows to the right that looks like this ">>". The icons I'm talking about are to the left of the arrows. Move you mouse over the icons until "download" shows up then click on that icon. This will load the manual into the Acrobate Adobe pdf file reader then all you have to do is save the manual to your hard drive. You will have to have the Adobe reader loaded onto your computer.

Once you have both operator and service manuals downloaded onto your computer then I recommend you spend some time reading them, especially the "Circuit Description" sections.

I have more manuals, TS-520, TS-820, and TS-830, plus others I plan on uploading to my website.

got an 820s from that auction site a few years ago...has been a great rig so far...
recently I have noticed a couple of problems when the shack gets cold....I live
in the mountains at 7,200 feet elevation & we have freezing temps well into May,
and yeah I do keep a small heater on for when it gets really cold, but the shack
can get down to the mid 40's at times...

#1) the S meter doesn't work until rig warms up for 5-10 minutes, then works OK
#2) it seems to lose lock in the PLL until it warms up for 5-10 minutes, then works OK...
cycling the band switch back & forth will bring it back into lock...have taken the rig
apart
& sprayed with De-Oxit which seems to work for a while, but would like a more permanent
solution...

anyone else seen/have these problems...if so, what was the fix ???

TIA...73 de Tom NM5TF

John

It would be best if you could get some help with this. Of course the help may not be familiar with cold neutralizing a KW hybrid rig or be aware of the shock hazard associated with the neutralizing capacitor. Must use an insulate tuning tool. Can use a heat shrinked screw driver, but the metal may affect the null. Can also make a tool from oak dowel rod by filing a flat tang on one end. The capacitor is stiff by design so it does not drift off where you set it.

Best to load rig up on 28.8mhz to approx 100 watts output and then turn off the SG switch on the rear panel.
Not likely that tubes will take off during this loading step.

A separate receiver that covers 10 meters can be used if you have no way to measure RF voltage. Ideally you would couple the output from the TS830 SO-239 connnector into the receiver antenna input using an RF Step Attenuator, but if you dont have one of those then can take a piece of hook up wire and cut each end flush and place tape over the ends so the bare copper cant make any contact and then slip the wire into each SO-239. This will serve as small amount of capacitive coupling for the RF from your 830 to the receiver front end.

You can then tune the receiver to 28.8 mhz and flip the 830 to Send and peak the Drive control for maximum S-meter indication and then adjust the neutralizing capacitor for lowest audio level in the speaker and the lowest indication on the receivers S-meter. If you cant hear or see the signal on the receiver go ahead and skin the insulation off just one end of your jumper wire so that when you plug it in to the SO-239 it makes electrical contact. DO NOT skin off the other end. You need the small (a few pf range) coupling capacitance to limit how much RF you are injecting in to the front end of the receiver.

Not the best method but it will work well enough.

John:

When I said to load up to approx 100 watts out at 28.8mhz I meant of course using a dummy load.

When done loading then turn off the SG switch and disconnect the coax jumper to the dummy load and then you connect your jumper wire (capacitor coupling) between the two rigs.

Make sure you do not turn the SG switch back on at anytime during this procedure until you have removed the jumper wire and re-connected the dummy load.

From: <wallydoc@...>
Topic: 48549 Message: 48554

John: Here is what I do:
tune the rig to full output at 28 MHz into a dummy
turn off the SG
using the 50 ohm dummy, put a scope across the pos and neg ant leads
I use a several watt resistor soldered unto an ant connector and connected to ant fitting
for scope reading, not tuning, easier to attach the scope.
Tune neut cap for lowest output on SSB, no mic volume.

It really bemuses me that people cannot or do not read.

Do you think I would spend a lot of key strokes to describe the receiver method of neutralizing if the OP had any test gear?

He clearly stated that all they had to work with was another rig and an S-meter.

Why not describe the old fashioned multiple keying method of trying to get the dip to match the peak output power method?

Terry K9TW

48557. Re: TS-830 getting new tubes

Topic: 48549 Message: 48557

So you are saying now you dont have access to another receiver (transceiver)?

Now I am confused. I thought you asked how neutralize new finals with only an S-meter as test gear? Was my explanation too cryptic? If so, then I agree you need to wait for help.

Perhaps Mike W5RKL will make a video demonstrating the receiver method and post on his new website? Some people do better when they can see something rather than to read how to do it. .

What operational symptoms do you have that leads you to think you need new Finals?

"Doc"

Couple of points (for new people who may be reading your counsel) :

1. There are no Positive and Negative antenna terminals on the rf output of the KW hybrids. There is a SO-239 connector where you connect a PL-259 connector that has the 50 ohm resistor connected in shunt to allow attaching your RF voltage detection devices.

2. Where in the Service Manual does it tell you to neutralize in SSB mode with the Mic gain turned down?

I think you are confusing that with balancing the LSB and USB Carrier Suppression levels. Depending on where you leave the rf voltage level for a given sideband neutralizing in SSB mode may present you with very little RF voltage to work with. The proper way to neutralize is as directed in the service manuals. This is performed in CW mode and not in SSB mode. In CW mode after loading to full output, turn off the SG switch, connect your rf voltage detection instrument to the PL-259 dummy load, flip to Send, using the Drive control peak the RF voltage detected across the mini-dummy load, and then null that voltage with the neutralizing capacitor.

I forgot one refinement in the cold neutralizing procedure.

After the first null get a hold of the Tank capacitor (Plate Tuning capacitor) and adjust it back and forth for a peak in the RF voltage. Almost always will get a peak in voltage after the first null. Then null this new peak with the Neutralizing capacitor. You can repeat this step 2 or 3 times. Typically after that you wont get any more appreciable increase in RF voltage.

Is this necessary? Of course not, but while you are there you can get the null as precise as you can at 28.8mhz. Neutralization is really only most effective at the band you perform it on and at the frequency where you do it at.

Early KW rigs and other mfg radios commonly directed neutralization to be done at 21.2 to 21.3 mhz. The idea here was to get some neutralization effect ranging from 14 mhz to 30 mhz. In practice it doesnt work well and best to do it at 28.8mhz where the Xc of the Cpg inter-electrode capacitance will be the lowest value resulting in more regenerative feedback and more likely for tube to take off.

Bob,
I'm giving the lecture on interfacing an SDR to the IF of the Kenwood hybrids (or any older radio).
I'm familiar with the "SoftRock SDR" kits, but I haven't tried one of the TV-Rx dongles. Does it have an VFO capability, or is it freq locked using a crystal oscillator? I use the HDSDR "free" software. Also, the 830's IF is pretty strong for my Softrock, and I need to attenuate the signal about 10db, I think.

Jan: Thanks for the prompt reply. Been a Ham for 55 years now, and one my first QST's had the article about the Q-5r - using ARC5 receiver as a tunable 455Khz IF! Years later, I hooked up my Kenwood TS-430 as a tunable IF to my Collins S1!

Now SDR. Native dongle SDR tunes approx 25Mhz to 1700Mhz, and there is a "Ham it Up" converter that allows coverage from 100Khz way up, with output above the FM Broadcast Band, so that usually the SDR tunes to 125Mhz. All controlled by software like HDSDR or SDR#.

So a few questions:

1. What do you do with the SDR & Kenwood...Panadapter, IF enhancement, or ?
2. Where and how are are you tapping the signal?
3. Any problems with the SDR during Kenwood Transmit?
4 Anything else I should know? I'm so new at this I don't even know the questions to ask. LOL

I got the dongle from an American dealer on the Bay, complete for $18! Converter runs about $50.

Thanks and '73

Bob / WA2JAJ

If this is too involved for the group, I can be reached directly at the e-mail listed below.

Ron

Are you trying to say that you are not responding to this thread and have a problem with your computer?

If you are using this thread to ask what resistors to replace on the TS-830 RF board that is not an easy question to answer. Also, I have never seen a bad driver tube socket, but often the soldering at the lugs where they penetrate the board is cracked due to poor original soldering and many repeated plug and un-plug cycles of the driver tube. This can cause intermittent RF drive problems. Also VC-1, VC-2, and VC-3 can have cracked soldering at the heavy lugs where the capacitor frames enter the board. This also will cause intermittent ALC indication.

As to resistors most of them would require lifting one end to measure. I guess I would look in the higher current applications. I have found driver tube screen grid divider resistors drift high and go open. I have 3 pristine looking R36 100k on the bench in last couple of months that test open. So I guess would look at R36 and R37.

Probably best way to check some of them would have been to take Driver tube socket voltages before pulling the RF board. Since you have the board out just look for obvious signs of overheating, but as I said these R36 resistors look like new yet are open circuited. Maybe look at R38 in the anode supply. Also, L36 driver tube plate choke can cause some problems on couple of the bands. I have replaced several of these. Sometimes can see a discolored brown or dark band around top 3rd of the green choke body. I measure them with digital LCR bridge.

Lastly I have replaced more than one block diode D1 in the Marker circuit. If D1 is bad will have lots of birdies in the receiver about every 10 to 20 khz with them being especially strong on 160 meters. You find them by placing rig on dummy load and Marker turned off and turn the VFO from 0 to 500. Diode D1 is mislabeled on the schematic. It is called out as a 1S1527 and that is wrong. It is a 1S1587 fast switcher. It is there to back bias the emitters of the Marker multivibrator on the PLL board to keep them shut off. If you look up a 1S1587 in NTE it calls out a NTE177 general purpose diode and that is wrong. A correct sub for a 1S1587 would be a common 1N914 or 1N4148 fast switcher.

That is about as good as I can tell you to check and/or replace while you have the TS830 RF board out.

I know several of our other members have been restoring older 1 million series 830s and have found carbon resistor problems so hopefully they will jump in here and share their experience.

Hope this is what you were looking for. Just remember dont be too quick to pull RF boards until you have taken some RF drive and Dc voltages. Lastly make sure you do a very good visual inspection of every Molex connector pin soldering. Must do that under magnification. If bad cant just reheat them. Must remove old solder, clean the oxide off the pin, and resolder.

Bob & the Yahoo Group,
It needs to tune very near to the 8.830 mhz IF frequency of the TS-820/830/530. If you have the 830, it's EASY. The IF is on the back panel (IF out #1), or rear panel item #11, in your owner's manual, page 12. Its an RCA jack that is there to connect to the SM-220. Connect your SDR receiver to it (as I mentioned, its a good idea to have about 3-10db of attenuation. I use a switching attenuator).
Watch this Youtube video, its very similar to what I do:
http://www.youtube.com/watch?v=UvG6QyRJW_A

I use mine strickly as a panadapter.
Transmitting has no serious impact to the SDR device or the computer. However, if I have the computer speaker volume turned way up, I get my voice coming through them (they are cheap speakers).

If I understand your SDR dongle, it's needing a converter to down convert from VHF/UHF frequencies, is that right? That sounds like a work-around solution to me ($18 + $50 = $68 !!!???). I like the "Softrock Ensemble-II Rx" (kit price $67; Built for $92 which is a great deal!)
http://fivedash.com/index.php?main_page=product_info&cPath=2&products_id=8
<http://fivedash.com/index.php?main_page=product_info&cPath=2&products_id=8>
With the Ensemble-II Rx, one can tune through the entire HF band. So, I can tune it to any of my radio's IF frequency (not necessarily a Kenwood radio) and accurately place the listening window exactly where I choose.
If you use the "Softrock Lite" ($21 kit + 8.812mhz crystal for 8.830IF $3.51), it will get you there too, but with NO VFO control (like the Ensemble-II will give you).
http://fivedash.com/index.php?main_page=product_info&cPath=1&products_id=5

Jan: Again, thanks for the info...checked out the YouTube and one or two others related to Kenwood. WOW! FYI - The dongle + converter combo I think can tune from 100Khz to 1700Khz...of course, you would need to have appropriate antennas to cover that range or portion! Question: If it were possible, on the '830, which IF would be better to use? I am thinking the lower frequency second IF...but since the jack is already set up for high IF, would it be worth the effort? Well, the initial stuff may be here as soon as tomorrow, so I'll be able set up the software and drivers...then I'll order the converter board. Took a look at FUNcube, but $200 not right now anyway

Thanks,

Bob / WA2JAJ

Bob

You are going to want to pull the IF off for a Panadapter in the IF chain Before they start tightening up the pass band. So would not want to tap off at 455khz where you are at less than 3khz wide.

In the hybrids they do that by inserting a xtal or ceramic "roofing" filter between the RIF amp and the Noise Blanker. This filter is approx 20khz wide and is needed for proper noise blanker operation. The IF tap for a panadapter is placed just ahead of this first filter in the IF chain.

I think you are going to want to look at approx 200khz of spectrum for it to be of real value. I think another good question for Jan is what kind of sound card is he using to ensure it has enough bandwidth.

Your mention of Q-5er brought a smile to my face. Dont hear much about Q-multipliers today even though the TS-830 actually has one as part of the Notch filter.

Topic: 48561 Message: 48570

Terry: Thanks as always, and right on the money.

In this case the Q-5r wasn't a Q multiplier, but used as a multi-stage tunable IF with very sharp selectivity. The ARC5 receivers had IF cans designed for user ability changing of the selectivity skirts by moving a slug in the IF can (not during use)! The low frequency ARC5 was very selective to begin with and included a BFO and audio amp so when using it, all of those features were by-passed in the host receiver,

One more question - Jan mentioned using a step attenuator. Since I don't have one, I was thinking about placing two resistors in series across the 830 IF output, 1 high value one lower as a sort of 90 - 10 tap or some ratio so as not to load down the IF while providing reduced output for the SDR. Any idea what the total resistance might be to start with...or do I go the lazy way and just insert a series resistor to reduce the signal?

BTW if anyone is interested, I have been accumulating information URL's mostly about getting SDR up and running and HAM applications..just let me know...a work in progress.

Thanks Terry,

Bob /WA2JAJ

Thanks Jan. And thanks to Terry, Mike, and all of the others who help us under very difficult conditions. Maybe The group owners should include a statement in the "Welcome Package" as a reminder that these rigs are not Plug and Play, and that remote diagnoses and repair, often without user training or equipment, is extremely difficult.

That looks very interesting indeed. What SDR software are you using? It is definitely different to the SDR#
software I use with mine and looks very handy for signal cleaning up.
My own self contained SDR radio uses an EZCAP "dongle" with my own design of up converter using an
FET double balanced mixer and a mmic IF amplifier with an FET RF stage.
It is so good that I rarely use my Kenwood now except when transmitting.
I can easily hear sub uV signals on it and find it very good indeed. My RX now covers 100 kHz to 1.2 Ghz except for 48 MHz which is my local oscillator for the up converter. BTW I have found that old TTL xtal oscillators can drive up to 10 TTL level loads and as a result can be used with high level mixers like mine.
However using one as an adaptor with the Kenwood looks nice. Not only that it is basically fixed on the Kenwood IF so no setup tuning would be required. Also no RF stage before the mixer just an IF filter.

It is not about meeting my standards.

It is all about a mentor or coach being able to use the correct technical and trade parlance and being able to read and follow directions and communicate that to new folks in a professional manner. This hobby is based on science and rf communications fundamentals. What we say and how we say it speaks volumes about our knowledge and abilities.

We are here trying to teach newly licensed people who entered the hobby today in very different way. They dont need to hear about the "positive" antenna connection on the back of their KW hybrid and they should be directed to perform steps in the service manual as written unless there is a proven alternate method that can produce the same results or the manual has proven to be wrong. Using a receiver to neutralize the finals is a perfectly acceptable alternate method. No where in the manual does it tell you to neutralize in SSB mode. There is a reason for that.

I like to set my standards and the expectations for the new people a little higher than curb height. I feel like I owe that to them.

Doc I understand that your heart is in the correct place, but I would be remiss if I did not concern myself with ensuring that new folks are learning how to talk the talk and walk the talk.

When they reach for a piece of test equipment and begin to measure they have moved from the qualitative realm to the quantitative realm and into science and not tribal knowledge, folklore or myth. Far too much of that exists in this hobby.

I meant no personal offense.

Just been following this thread!
Now my SDR simply plugs into a USB2 port and everything gets done there.
All mode demodulation bandwidth and AGC setting and an RF and AF gain
control for the received signal. Of course I also have a RF gain
control on my external unit. How is this SDR system actually connected
to the computer and how many ports does it require?

Terry,
When measuring RF voltage on the SO-239, are you talking about a volt meter with an RF probe?

John

It would be best if you could get some help with this. Of course the help may not be familiar with cold neutralizing a KW hybrid rig or be aware of the shock hazard associated with the neutralizing capacitor. Must use an insulate tuning tool. Can use a heat shrinked screw driver, but the metal may affect the null. Can also make a tool from oak dowel rod by filing a flat tang on one end. The capacitor is stiff by design so it does not drift off where you set it.

Best to load rig up on 28.8mhz to approx 100 watts output and then turn off the SG switch on the rear panel.
Not likely that tubes will take off during this loading step.

A separate receiver that covers 10 meters can be used if you have no way to measure RF voltage. Ideally you would couple the output from the TS830 SO-239 connnector into the receiver antenna input using an RF Step Attenuator, but if you dont have one of those then can take a piece of hook up wire and cut each end flush and place tape over the ends so the bare copper cant make any contact and then slip the wire into each SO-239. This will serve as small amount of capacitive coupling for the RF from your 830 to the receiver front end.

You can then tune the receiver to 28.8 mhz and flip the 830 to Send and peak the Drive control for maximum S-meter indication and then adjust the neutralizing capacitor for lowest audio level in the speaker and the lowest indication on the receivers S-meter. If you cant hear or see the signal on the receiver go ahead and skin the insulation off just one end of your jumper wire so that when you plug it in to the SO-239 it makes electrical contact. DO NOT skin off the other end. You need the small (a few pf range) coupling capacitance to limit how much RF you are injecting in to the front end of the receiver.

Not the best method but it will work well enough.

Gents

Out of interest, the Saturday net frequency is out of band for UK amateurs.

Current bandplan can be found here

http://thersgb.org/services/bandplans/html/rsgb_band_plan_jan_2014-1.htm
http://thersgb.org/services/bandplans/html/rsgb_band_plan_jan_2014-1.htm

Upper limit for UK users is 7.200Mhz, with amateurs having primary use of 7.100 to 7.200,
Can listen, but would be naughty to transmit...

Alan

Hi Glenn:

Yes to measure and adjust RF voltages anywhere in the KW hybrid radio (Carrier Osc, Het Osc, VFO, VCO, RF drive levels, Product Detector carrier null, Balanced Modulator side band suppression/balance etc) you need one of the following instruments:

1. VTVM and RF probe or DMM and RF probe or FET based analog meter and RF probe. I prefer analog meter for peaking and nulling but absent that can use a digital meter. The RF voltage in the case of neutralizing will be at 28.8 mhz and the VTVM or DMM ac ranges wont read that high so you must rectify that ac voltage (varying at an radio frequency or RF rate) and read it on the meters dc ranges. For neutralizing the VTVM will need to be set on typically the negative 1.5vdc range.

For neutralizing a 1 diode probe will work just fine. About maximum RF voltage you can read with a 1 diode probe is approx 30 volts without destroying the diode. If you are going to use VTVM and RF probe for KW work need two probes. A single diode probe and a 3 diode probe. .

2. An oscilloscope and a scope probe on AC mode. No need for any kind of a detector. Preferably an O-scope with sufficient bandwidth. I wouldnt use an old 5mhz audio scope to look at 28 mhz signal. If all you have available of course give it a try.

3. An RF millivolt meter. This is the best and easiest meter to use, but not commonly owned unless you are serious repair man or builder/experimenter. The RF millivolt meter has diodes built in to its probe. Most can read max of approx 3000mv so have to be careful not to burn out the probe. Must have a 40 dB or 100:1 capacitive divider to make it a complete instrument.

Mike W5RKL and I have previously recommended that all new folks make a VTVM and RF probe their first test gear purchase. Can buy a RF probe or homebrew one.

Terry K9TW.

Glenn

I forgot to mention you should terminate the SO-239 with a 50 ohm mini-dummy load if you cannot get access to measure the IR drop across the resistor in your high power dummy load.

Easiest thing to do is to solder a pair of 100 ohm resistors across a PL-259 uhf plug. Leave resistor leads long and solder from center pin to the shell. Now you can connect your RF probe across this 50 ohm load and measure the RF voltage.

Terry

Or dig around in the junk box (or a local-ish supplier of salvaged bits) and find or make a very small switch with which you short across TWO of the three diodes in your three-diode probe, making it in effect a one-diode probe for the duration of the switch activation. Saves the fuss of making two probes.....

I made mine inside a "Sharpie" marker body, gutted of it's marker ink supply, lined it with aluminum foil for an RF shield, made a probe of a decorative copper nail, used shrink-tubing on all the components (0.01 uF capacitor, 4.7M ohm resistor, three diodes), and added the smallest pushbutton (PBNO) that I could find at Gateway Electronics in St. Louis, Missouri.

The only thing the button does when pressed is short across two of the diodes in the string of three.

Without pressing the small button, it's a 3-diode probe. Press it, and it's a one-diode probe. Simplicity itself. Seems to work just fine, too.

Wes:

Yes good way to approach if you want convenience of a single probe. I like the pushbottom in the fail safe position as opposed to a miniature slide switch that could be mis-positioned.

In both cases just have to remember where you need to use the multi-diodes. Plate of the Driver tube, control grids of the 6146 Finals and across the external dummy load at 100 watts out (approx 71 rf volts). Same with 2 probes have to remember which one to reach for and as Will notes not as convenient.

Of course on the opposite end have to remember with 3 diodes in have to overcome barrier junction of approx 0.25v per diode so wont see anything on your meter if you try to measure TIF signals for example.

Just remember the diode sees the peak of the rf voltage so that is why I suggest not to use the single diode to measure over approx 30 rms rf volts or approx 42 peak volts. Depending on the diode you use could have higher PIV but the 30 volt rule is good one for safety margin. I believe Heathkit says not to measure over 90 volts with their 3 diode PK-3 probe.

If you have never homebrewed anything the RF probe project is a good first one. Take a look at the Classic N5ESE information.

Hi Terry and Glenn,

Been under the weather, sick with Bronchitis, still no where near out of the woods.

I have a video on my website that shows some of the "basic" test equipment for those members who have never owned and operated simple basic test equipment. The video can be viewed at the following link:

http://w5rkl.com/wp-content/uploads/2014/03/Examples-of-basic-test-equipment.wmv

I also have a video that shows how to use a simple DMM/DVM to measure voltage drop, current, and voltage in a simple series resistor circuit. I also talk about using ohms law to "paper/pencil" calculation that comes up with the voltages, current, and voltage drop shown on the video then follow that by using the DMM/DVM to prove the calculations. The video can be viewed at the following link:

http://w5rkl.com/wp-content/uploads/2014/03/Using-basic-test-equipment-to-measure-voltage-and-current.wmv

The resistors in the above video are small, 1/2 watt carbon film, and are difficult to see but they are wired on the breadboard as I say they are. The circuit drawn on the paper shown in the video is exactly the same as the 3 resistors in series across the 12VDC supply on the breadboard. I measured each resistor individually then took the time to draw the circuit on paper so you could see. If you want more videos on series, parallel, and series/parallel resistor circuits, I have videos on those as well. Simply go to

www.w5rkl.com

and click on the basic instructional video link.

There is something the series resistance video using the breadboard does not say. The DMM meter when connected to measure the circuit's current the meter displayed .187 as the current flowing in the circuit. The DMM was set to measure a maximum of 2ma and when the display showed .187, that's actually 187 micro-amps. It takes 1000 micro-amps to make 1 milli-amp. The same is true where it take 1000 milli-amps to make "1 amp". Learning this is very important otherwise your measurements and/or Ohms Law calculations will be wrong.

48593. VFO-240 Dial Lights

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-20 23:20:32 UTC
From: <halitousis@...>
Topic: 48593 Message: 48593

I just added a vfo-240 to my station. After determining that it operated correctly I noticed that it appeared that one of the dial lights was not working. When I removed the top I was very surprised, I don't know what I was expecting, but it certainly was not what I found. A big empty box with a self-contained vfo, a switching network and a lot of empty space. How much of a job is it to change the dial lights. Would it be the same procedure as the ts-530s. Looks like access is the big issue.

Bill,

I think that you should be able to remove the 4 screws on the front that hold the VFO in place and slid it forward...the bulbs...I believe are the same as used in the 820 through 830 series
of the KW hybrids

Bill,

Very straight forward to change the bulbs. From memory all you have to do is unscrew the front 4 screws and slide the VFO out, normal change over for the bulbs from there. Ken K4EAA has replacements and are very good.

Mike and New Folks:

I am sure Mike is aware about meter "burden". I have spoken about it here before. Some of the newer folks most likely do not. Quite often the measured milliampere current displayed on a DMM wont be accurate and wont agree with the circuit calcs as the meter is dropping the supply voltage to the circuit.

Ideally when we open a circuit and insert a DMM we would like for that meter to look like a dead short but unfortunately the meter has resistance (impedance) from the leads, the fuse holder, the internal switches etc. which will result in a voltage drop across the meter. With DMMs (especially cheaper low end units) this can be pretty significant. The higher the DMM burden voltage the higher the error in current measurement.

Most folks dont know about it or what the actual burden of their low end DMM is. Most better DMM spec sheets list the burden voltage. Low end ones may not. Some are pretty bad. A high end meter might have a burden voltage of 1.8mv/ma. Might seem odd to be talking about voltage, but that is all any meter really measures.

This means if you are trying to measure 190ma on the 200ma range of your DMM with a burden of 1.8mv/ma you would mulitply 1.8mv x 190ma = 0.342 volts. The DMM itself is dropping 0.342 volts of the circuit supply voltage. So if your test or demo circuit has a 5vdc supply powering it the circuit will have only 4.66vdc available.

You can work the math to see what that voltage drop does to the test circuits current consumption and the error it introduces.

Sometimes it is better to break the circuit and insert a precision .1 ohm resistor and measure the IR drop across it and calculate the current.

I only mention this for new folks who might be tempted to buy the $9.95 Harbor Freight DMM and not realize it has couple of limitations.One being approx 900k input impedance as opposed to 10 to 11 meg ohm and the other having a pretty high burden voltage on the DC ma ranges. I cant remember what it is but it is high.

For most of your KW hybrid work you will never be measuring dc ma circuit currents. I do a little of that and have recorded normal loads for 9vdc regulator, VFO current draw and a few other places, but far more common to measure dc voltages.

So when you buy a DMM suggest you buy as much Speed and Resolution that you can afford and make sure it is a 10 meg input Z meter on all the DC voltage ranges. Also, be aware of the burden voltage so you can be aware of the accuracy limitations of DC ma current measurements.

If you search on You Tube can find some good videos about DMM burden voltage.

Terry K9TW

48597. TS-830S audio distortion cure

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-21 16:15:20 UTC
From: Craig Roberts
Topic: 48549 Message: 48597

There has been one characteristic of my TS-830S that has annoyed me from the outset: receiver audio distortion on strong signal voice peaks. My TS-530S has always sounded cleaner and more 'transparent", as the say in the audiophile world.

I have read that replacing the OEM diodes D20-23 on the IF board with Schottky devices can help clean up the TS-830S receive audio. I have also read that the exercise is useless and not worth the trouble. The sum of these two points of view, a far as I could see, was "can't hurt", so I performed the surgery this morning. Here are my observations:

1) this is NOT a troublesome operation. Swapping the diodes takes about 20-30 minutes with at least some of the time spent in removing and replacing the radio's top and bottom covers and removing and replacing the hold-down screws on the IF board. Once the board is loose, stand the radio on its right hand side and carefully slide the board a couple of inches up off the edge of the chassis to expose the cluster of diodes. Handily, they're right on the edge, so there's no unplugging of Molex connectors or cables to be done.

Remove the stock diodes using Soder-Wick or -- MUCH MORE PREFERABLY -- the extraordinarily handy Hakko 808 desoldering gun as endorsed by Terry Wagoner. With the Hakko, removing all four diodes took fewer than 30 seconds with no danger to the rather fragile Kenwood circuit board traces. If you do much electronic repair and restoration work, this desoldering gun is a MUST HAVE!

2) In my case -- and I cannot speak for anyone else -- the diode substitution DID improve received audio noticeably. Now, my TS-830S is an early, 1-million series radio so MAY have had more "room for improvement" than later models with an upgraded 2nd IF filter (Murata CFJ455K12 vs. the earlier CFJ455K5). I have no idea if the later filter made any real difference in received audio. Just sayin....

To be honest, my TS-530S receiver audio still sounds better than my 830's, but the difference is not nearly as dramatic as it had been. In fairness, it should be pointed out that the 530's receiver is single conversion, which sounds nicer on the low bands than a double or triple conversion radios (according to anecdotal sources, anyway). Another big factor in the audible difference between my two KW hybrids is the SSB filter bandwidths. The 830 utilizes the stock 2.4 KHz filter while I have outfitted the 530 with a couple of terrific Inrad 8-pole filters, including the wider 2.8 KHz SSB model.

Still -- and I emphasize that this is my personal experience only -- the easy-to-accomplish TS-830S diode swap has been worthwhile. If you, too,

have been disturbed by a harsher than desirable audio response from your TS-830S receiver, this half-hour operation may prove useful.

The Schottky diode set is available from Ken Kemski, K4EAA, as part # SD-400.

73,

Craig

Hi Craig:

I think that even without measuring you are 100% correct that the 530 and for that matter all the other hybrids have better sounding receive audio to most folks ears. I have had people ask me who were long time TS520 owners if anything they could do to make their newly acquired 830 sound more like their 520. I must admit that the old 520 with its discrete device OTL circuit does sound better to my ear. So I suppose if most of my operating was rag chewing on 40 and 80 I would prefer more bass presence.

I think we have to remember the full filtered TS830 was really designed as a contesters radio and a CW contesters rig at that. It can still hold its own today in that service.

Of course you know you can adjust the carrier oscillators for a more bass response.

Also there are some mods out there that change out the Low pass filter components in the output of the Product Detector when you are in there swapping out the diodes. If you look at this CRC pi-filter on any of the hybrids will see different values. There are some online calculators that can help select values for given cut-off.

I have also seen some recommendations to change the input and output capacitors in Q4 audio output HA1368R device circuit. The data sheet shows how to select capacitors for given frequency response. I have never done any of these mods and my ear is not sophisticated enough to make any recommendations.

You of course are also correct that the Hakko almost makes childs play out of desoldering and almost eliminates chance of lifting a pad. I say almost as you do need adjust the temp control and not linger! It is real fun to have IC chips literally fall off the PLL board! The amount of work I do I could not function anymore without one.

Topic: 48593 Message: 48599

I tried extracting the vfo out the front, encountered more resistance than I felt comfortable overcoming. I removed the dial, than removed the front panel and removed the vfo from the back of the panel. Complete access and no undue resistance to overcome. Waiting for Ken, K4EAA, to send replacements.

Hi Jan

Now that's a thought.... how would I go about doing it?

Would I be limited to rx only, or is there a way I could 'transmot' as well?

Out of interest, could anyone record a net and post it on, say, youtube? Would be great listening in and putting some voices to names!

Greetings Group,

Over the past few days, it appears that at least one member of this group has had their "AOL" email address hacked/hi-jacked. Both are listed at "QRZ.com" and have valid operating licenses and the "spam email address" matches with the ones listed for them. Please... DO NOT OPENANY EMAIL FROM THEM. I am sure it is not their fault...but you need to be aware:

KD4QFT@...

KA2VBT -- jmo1241@...

AGAIN: I do not place blame on them...just the a..hole that hijacked the addresses

I get great value and help from this group but I sure wish it was a proper forum with threads and posts. Simply because it would make finding the gold contained in posts so much easier to find and accessible. Probably cut out a lot of FAQs and annoyance of similar questions that have already been answered.

The format of yahoo groups with topics and conversations makes searching convoluted as opposed to threads and replies. I'm not having a crack at the group , just the yahoo group mailing list format is not to my liking. If there was any thought being given to an alternative to yahoo, I would be all for it, especially as yahoo can and do make major changes without much if any notice.

I would stop bothering with it if the mailing list was moved to a forum. They're too confusing and hard to use, with all the new "posts" scattered around randomly so you have to hunt for them.

Forums just don't make sense.

Christopher,

I am a bit confused regarding the above post.

ANY member can go to the "home page" of this group and search "conversations" regarding any topic that may have already been discussed. I agree that it may be time consuming but, I do not have control over how yahoo runs their end.

So, go to the this groups "Home Page," and you can click on "conversations," and enter what you are looking for...for example: "TS-830 low power output" You will be rewarded with
LOTS of conversations/threads regarding this topic. You may also go to the "FILES" area also accessible from the home page...lots of information there too.

Could it be better...yes...but ...as the lame phrase goes...."I only work here."

Craig:

I had a fellow contact me yesterday and ask if I would work on a Kenwood R2000 receiver. I have never seen one. I told him I would look at the schematic and see if I could give him some email troubleshooting help.

Looking at the schematic I notice that it uses the same HA1368R audio output device as the TS830. One difference is that instead of a 220uf output capacitor it uses a 1000uf cap. I suspect they went to this value as the receiver has an AM mode?

I plugged the values into one of the on-line coupling cap calculators and here is what I got:

1. 8 ohm Speaker
2. 220uf output cap
3. -3dB frequency = 90.43 hz
4. Optimum low frequency response = 904.29hz or approx 1khz

1. 8 ohm speaker
2. 1000uf output capacitor
3. -3dB frequency = 19.89 hz
4. Optimum low frequency response = 198.9 hz or approx 200hz

If you parallel up a 1000uf with the existing 220uf then Optimum low frequency response would be approx 163 hz.

As I said I have never seen or operated a R2000 so cant speak to the audio response on SSB signals.

You may want to try to parallel up a 1000uf cap across the 220uf on your audio board?

Hey Terry, et al,

Well, I had a 1000uF 16V 'lytic on hand, so i substituted it for C34 (220 uF 16V) on the TS-830S AF board.

As your calculations predicted, Terry, it opened up the receiver bass response noticeably and quite pleasantly due to the added "warmth." The difference is especially dramatic when high fidelity headphones are used.

Great suggestion, Terry. I'd recommend this simple mod to anyone who'd like a bit more bottom end on their received audio. My next move -- as soon as the parts arrive -- is to install a set of 2.7 KHz SSB filters in the radio. I'm looking forward to that.

Craig;

I am not an audiophile (cant spell euphony!), but have done a little reading on coupling caps and speaker caps. You can Google on speaker coupling caps and will find endless discussions on audio grade caps and some prices that will knock your eyes out.

Mouser and others sell audio grade capacitors. Who knows the condition of the cap you had in the junk box. Maybe bring up a couple of terminal post off the audio board where you could tack in different output caps without folding board over and risks of multiple unsolder/solder operations.

Having VBT control should make 2.7khz xtal filter viable option. Never tried it.

Terry:

Well, my 1000uF 16V coupling cap is new, so no problem there. According to my friend Dennis Had, W4USR, this particular electrolytic should be sufficient in its role.

Denny knows about such things. He is best known in the ham community as the founder of Dentron -- maker of pretty nifty linears and antenna tuners from days of yore. After selling his amateur radio enterprise, he went into the audiophile business (more lucrative, we can imagine) as Cary Audio Design, manufacturer of very high end tube-type audio amplifiers for rich guys. Denny retired a few years ago but still builds experimental amps for grins and has fun upgrading the audio sections of Drake TR-series gear with the aforementioned audio grade caps.

I like your "plug-in" idea, Terry. I may just do that. I am anxious to try the 2.7 KHz SSB bandwidth mods on the 830. As I've mentioned before, I equipped my 530 with an Inrad 2.8 KHz sideband filter (and a 400 Hz CW one, too) and it sounds terrific.

Craig:

Another thing which you may be aware of is the internal "toy" speaker is limiting as well. An external speaker is an easy enhancement. I always run my TS-830s rigs on the SP-230 remote speaker when not using headphones. I have always wanted to experiment with a DSP speaker, but havent gotten around to it. Some pretty impressive You Tube demos.

Hams since beginning of time have been modifying commercial gear. Heath HW-101 comes to mind. Sometimes those mods even get adopted and incorporated by the manufacturer in subsequent model years. I generally am not too much in favor of modifying the KW hybrids and some people have no business attempting it. Seen some pretty ill conceived and very poorly executed mods.

Changing an IF filter or a speaker coupling cap is pretty innocous and well within the spirit of ham radio days gone past.

With that being said I think you can tell I am not in favor of eSSB or opening up the IF shift or VBT. People do this without thinking about effect on carrier suppression. Of course very much against any and all "hot rodding' or "QRO" mods to gain a few watts output power. I still run into some of the old Magi-com mod boards from time to time.

Only mods I have in my own rigs is final tube arc over protection. Just my personal approach.

Have fun.

I agree with you, Terry. I am of the opinion that the design engineers know a WHOLE lot more than I do about component selections and limitations.

Nevertheless, I do like to mess about with benign audio mods. I has something to do with being an old broadcaster. However, like you, Terry, I am not a big fan of eSSB, though I do marvel at the fidelity of some of the signals I have heard recorded. For me, it's a matter of courtesy to fellow sideband operators. Want to sound like a radio personality? Buy or build an AM rig and hang out with the chatty boys on 3.885.

That being said, I just finishing retrofitting my TS-530S with a 1000uF coupling cap on its AF board, too -- just as I did last night on the 830. Wow! Coupled with the 2.8 KHz Inrad filters, the audio is warm and full. Very, very nice.

Incidentally, I too use the SP-230 outboard speaker or -- better yet -- my 120 watt audio amp and studio monitor speakers.

OK I am going back to the bench before you trick me into the inevitably next step of debating the merits of bypassing these new 1000uf electrolytic speaker caps.

I think KW design engineers quite appropriately put the small value bypass capacitors where low impedance was needed at the two 900vdc HV filter caps and that is all I will say about that!

Oh and those resistors where we attach those small disc ceramics are more appropriately called "equalizing" or "balancing" resistors and not "bleeders", but now I digress!

The next time you are in the PA cage pull the front 6146 tube and lube the S22 switch detent balls. After 35 plus years not much lube left on the balls or detent path.

I first clean them off with alchohol (Everclear!) applied with artist brush and rotate several times. Blow dry with canned air. Then using artist brush or sharp pointed toothpick apply small amount of PTFE based grease to each of the detent ball bearings and rotate several times. May apply another small drop on each and repeat one more time.

I use Magnalube G which is kind of expensive. I like the Magnalube because it is very high dielectric and high temp. I am lucky to have a small tube of it left over from my boys motorcycle days.

A good sub might be Super Lube. Absent a PTFE based lube can just use Lubriplate.

Just dont apply too much. I rotate the switch so the ball is facing me and can place it between 2 detents to expose more of the ball bearing surface.

Hello All.

I have a few extremely nice pieces of Kenwood gear I reluctantly need to sell. ALL pieces are As New both cosmetically and electrically. The following is what is for sale:
TS-830S zero flaws $600 (electrically checked in 2013) Silk smooth tuning LOW Hour back up unit
SP-230 Very Nice $125
MC50 zero flaws (No discoloration of switches) $100

RARE R820 in extremely nice shape. Needs only the dial bulb replaced. Comes with the kit to mate with TS-820. Loaded with all optional filters. $800 + shipping

Units are all boxed in storage and can pull from storage to supply pics if serious interest. .

Shipping extra. CONUS Only

Yes you are not alone to just focus on the contacts.

Many folks do a lot of spraying "at" as opposed to "in" through out a KW hybrid. I apply the Deoxit to the S22 decks with artist brush to the wipers on each deck and cycle repeated times. If especially black I use a drop or two of D100L. Kind of expensive, but does a great job. Awful lot of D5 being wasted and left soaking plastic and phenolics.

Lubing the detent ball bearings really makes the operation smooth. Of course you want the positive detents, but all electronic rotary switches come with the detent balls and race lubricated from the factory and it can dry out over the years. Many many years ago we would use Andoc and the military speced a lube for all their rotary switches. Just dont want to use anything conductive or that will migrate and less is more!

No rush to do it now. Maybe in a year when you do a spring tune up and blow the dust out and lube the fan bushings and perhaps rotate in your spare finals.

Have Fun

Terry,

Thanks for the reply.

Hoping I would draw some interest from group before listing on QTH.com.

I need to retreive some info on the 830S, so I will forward the serial number.

Side note: I have a lot of liturature and the original manual. I do not have the original Kenwood carton.

I have had the radio for many years, second owner. The radio gets very little use and really is a show quality unit. I have some misc spare parts for it as well. Shaft coupling, bulbs etc.....

Thanks for interest.

Ray

48627. My TS-820s and a question or two (a hum, a "gritty IF", and tuning)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-28 03:15:44 UTC
From: <les@...>
Topic: 48627 Message: 48627

Now that I have had a General license for about 3 weeks, the rig has been getting a real workout and I cannot be more pleased with her!! 2 of my questions, probably quite normal operation for a 35+ year old rig, I just don't know, so I figured I better ask. My 3rd question, is me wondering if my (bad) habit might be doing some damage.

So, here goes;

1 - I've noticed that if I turn the AF gain up beyond 4'ish, when I key the mic, there is a hum, like feedback (higher AF gain = louder hum). If you have ever turned on the the "moni" and listened to yourself without headphones, this is what it sounds like. An external speaker plugged in to the rear does the same. Headphones in the headphone jack, no issue at all - I can make my ears bleed and turn the AF gain full while keying up all day. Normal or do I have to think about a cap or two replacement soon? Does this with a D-104 (properly wired), an MC-50, or no mic at all (using the send switch. The rig is correctly tuned up and functioning well other than this little "feedback".

2 - The IF Shift feels just a little gritty when turned almost fully CCW. Should I try to hit it with some de-oxit or similar or just not worry about it? I have been pulling in some real good DX with the rig and I can really bring them in by using the IF Shift, as you know - tends to cut right through the QRM.

3 - Sometimes when I switch bands, I forget to set the plate to the approx band before I start the tune process. As soon as I flip to IP and go to adjust the plate, I note my error and start over. Is this brief drive peaking with the plate set to an "improper" band doing any harm. The send/rec switch is only in send for a brief moment and it is always while mode is in tune.

I understand the rig pretty well, but with that said, I know I am far from the expertise and experience of those more knowledgeable here on this group. If my questions have exhibited my inexperience, well - that's a little bit of what it is. My questions are so I can gain some knowledge from those that know!! Please accept my thanks up front!!

More questions next time about my antennas and tuning. I know you are just chomping at the bit for those questions, so stay tuned....

Thanks!!

48629. TS-830S Antenna and Mixer coils

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-28 11:46:44 UTC
From: <puttinggreen@...>
Topic: 48629 Message: 48629

After being away from the hobby for over a decade, I found that my trusty ol' TS-830S had not liked being ignored for so many years.

After replacing the HV caps, the driver and screen caps, the RL-1 relay, and a couple resistors; the output came back to 95+ watts on all bands…except 80 meters. On that band I had no ALC reading during tune-up and only 15-20 watts out.

When I went to adjust the coil pack, I noticed both the mixer and antenna coils for 3.5 MHz had disintegrated (L5 and L14). There was hardly anything left to either adjusting core. I pulled the RF board out and removed both 7mm coils. They were identical with the same markings and in the service manual they had the same Kenwood part numbers.

What is the accepted practice for this kind of repair? It seems these shielded variable inductors are getting harder to come by and initially I found them difficult to identify. Several choices came to mind:
- Look for a Kenwood Hybrid Guru that was willing to take two 80 meter coils off a parts board that he had squirreled away somewhere
- Try to find a similar coil with exactly the same core material and thread that would fit into my two Kenwood coils.
- Order Amidon L-33 shielded coils from http://www.amidoncorp.com to replace these 7mm inductors and wind my own… (If I needed 10mm coils I would order the L-44 shielded coils.)
- Take a good guess at what the coils were and look for new ones

I took the last approach. Pushing the biggest piece of core I had left through the coil with a toothpick, I measured the inductance range. It was only a piece of the original core, so I added some extra inductance to my readings and ordered new coils from Coilcraft http://www.coilcraft.com http://www.coilcraft.com/ They were 8.2 uH coils part number 7M3-822 and cost $3.66 each. They would have cost only 62 cents each if I had wanted 5000 of them.

The new coils adjusted up well and my TS-830 has full power on all bands now, but I am left with two questions for the group:

The TS-830 has 27+ of these mystery inductors on the RF board listed in the service manual only by the Kenwood part number. Is there a listing somewhere that identifies them all…not by manufacturer necessarily, but by what they are: inductance, range, Q, etc. This list would be a great addition to the group's Files section.

And the other question: Are there any other alternatives in repairing these broken cores and/or coils that I have not listed?

Herb Watson – AA1IY

Les,

Your points :
1) Hum is not normal. Maybe due to RF feedback. All bands? Does it vary when tuning-up? What the rig feeding? Try a good dummy load directly connected to rig to see if it still hums.
2) Try Deoxit. Let the solvent evaporate before energising.
3) Brief mismatch in tune is OK but get into a correct routine for tuning. Also make yourself tuning charts.

Stay safe
Dave f4eyk

Mornin' Herb,

As you can imagine, or will soon discover, RF Boards for the TS-830S are very scarce but you MAY be able to cannibalize an RF board from another Kenwood radio. Boards are often available on eBay (there's one from a TS-430S listed now, for instance). You'll have to download a service manual from the "donor" radio to determine if it shares the coils in question, of course.

Best of luck,

Craig

Topic: 48627 Message: 48632

The rig does this with three different antennas, one being a home brew end fed random wire for 10 meters, the other two are end fed dipoles (one for 20, one for 40). It also has the hum when tuned into a dummy load. The "hum" is identical on all bands. The hum only varies as the AF gain is adjusted. Is the lack of any feedback (0 feedback hum at all) while using headphones an indication of any specific circuits?

Thanks!!

Herb,

I once had a heap of old CB radios and based on the era of those radios and that of the 830s\530s, I managed to pull a few of the slugs which are a good fit. The slugs were identical in length and on a comparison after I replaced the slugs they seemed to be within a 1\32 of the original depth, once re-aligned. But over here it is getting harder to find the old CB's for tech speical prices.

Hi all!

I picked up a very nice TS-830S with an MC-50 and SM-220 at a hamfest a couple of weeks ago. Wish I could have picked up the rest of this very complete and clean hybrid station. It was from an SK estate and must have been resting for a long time as it shows very little usage. The WARC bands hadn't even been enabled. ;) Since these rigs don't like inactivity, it needed the usual switch, pot, variable cap cleanup. The shaft couplers and nylon gears show no signs of cracking. The shaft couplers in the SM-220 did, so I replaced them as preventive maintenance. Other that what I am assuming is normal warmup drift with the BS-8, it is also fun to use. The net check in that I was able to make last week got good reports. It has taken the place of honor from my TS-820S setup...

One thing that I am looking for is the cap nut that goes on the bias pot. For some reason it is missing and I have already bumped it once. It's not the same as the one on the TS-820S.

Is the VOX off?
Yes

Is the Moni off?
Yes - but the symptom mimics what would happen if you had the moni on - feedback through the speaker. I've attempted to rule out any inaudible signal by using a different mic, muffling the mic and speaker (put my hand over them) and removing the mic completely. "Feedback" continues at the same level regardless of manner of muffling.

Using the Phone patch jacks?
No

Have you tried an external/remote speaker?
Sort of - wired up a few different computer speakers for the rear ext speaker jack - they have the same exact result as the rig speaker.

Thanks!!

Les

Tuned into dummy load, no change when CAR is adjusted - nice steady hum as the carrier is adjusted up or down. Only thing that seems to cahnge the hum is adjusting the AF Gain up or down.

Well ordinarily I would suspect bad power supply filter capacitors if you have 120hz "hum". What confuses me is the feedback that you report that mimics having the Moni turned on and the audio output to the Speaker instead of the Headphones.

To me the sound of feedback that I am familiar with is very different than the sound of hum.

Just so I am certain you say that there is no HUM or FEEDBACK when you are on the Headpones. Is that correct?

Maybe a You Tube video is in order so we can hear what you are hearing?

Topic: 43005 Message: 48643

Ah, antennas. While I envy the guys in Europe who -- mysteriously -- seem to be able to afford a "seven element 40 meter monoband Yagi on top of the mountain I own" or the fellas out west who have the real estate to set up a "Sterba curtain on 80 with an eight element phased vertical array for 40 with stacked 5 element monobanders for the higher bands" (and they're always running 2 KW, anyway).

I, like many of we mortals, am operating barefoot out of a small suburban lot.

Several years ago I built an experimental Moxon antenna out of PVC pipe and aluminum tubing. It worked very well and I got many requests for plans after it was featured on an antenna junkie website. The problem was that it was only for 20 meters. To augment it, I slung a dipole up for 40, which just barely fit from corner to corner on my property. Wanting to work more bands, I took down that pair and tried an all-band TTFD (tilted terminated folded dipole); a configuration derived from a WWII era radar antenna. As promised. it loaded up on several bands 80-10 -- but basically because it presented dummy load-like impedance to the radio with not dissimilar results.

Then, about a year ago -- just about the time I became a Kenwood hybrid devotee -- I strung up a 55' long doublet fed with ladder line at about 25' AGL (above ground level). It needed a tuner, so I built one consisting of two identical 19 uH roller inductors synced with a pair of miniature pulleys and timing belt followed by a 250 pF transmitting variable cap. With this thing, mounted on a hunk of pine wood, I can tune any frequency from 7.0 to 29.0 to an SWR of 1:1 to 1. If I switch in a variable cap ahead of the homebrew tuner (courtesy of my AT-230 tuner which also acts as my wattmeter), I can work 80/75 meters as well.

As modest and a simple as this antenna setup is, I get consistently flattering signal reports on all bands-- usually S9 and above, more often 10 -20 dB over 9. The good performance (the overall best I have had with any multi-band antenna in 44 years) may very well be due to the fact that I am feeding the antenna with homemade ladder line which is virtually lossless at the 45 foot shack-to-feedpoint length I use. Also, there are no connectors on the antenna. Each side of the ladder line and doublet are one, continuous length of #14 insulated wire; the two sides separated at the feed point by a simple center insulator. At the shack end, the two feed line elements are connected directly to the tuner's variable cap -- one side to stator, the other to rotor.

Oh -- a balun is needed between the radio and the tuner, but that's simple. It's a so-called choke balun; about 30 feet of RG-58u coax wound

around a 4-inch cardboard mailing tube. It works perfectly and, as a bonus, cured all my "RF in the shack" ills.

By the way, if anyone's interested in building a similar tuner for balanced feed lines, I have a pair of matched roller inductors and a new transmitting cap for sale. "Enquire within."

73,

Craig

"Just so I am certain you say that there is no HUM or FEEDBACK when you are on the Headpones. Is that correct?"

Correct.

Maybe "feedback" was a bit of a misleading way to identify what is happening - that's why I tried to "quote" it every time I referred to the suspected problem. To me that was the best way I could think to describe the sound. During normal usage and I turn up the AF Gain, say to hear a weak station, if I do not turn down the AF Gain before I transmit, a noise that sounds like feedback (to me) is heard (through the speaker. If I am using headphones, I can turn the AF Gain full blast!). If the AF Gain is above approx "4", this happens. As you know, normally, a setting of "4" is quite loud to begin with. Recently, I have been getting some decent DX contacts, but I have had to turn up the gain to hear them and that is when I noted the "feedback"

If you want, we can meet on the air - I'll bet the "feedback" gets transmitted. Otherwise, I'll see if I can come up with a method to video this for you.....

Thanks again for everything!!

48646. Neutralizing TS-530S after many years of use

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-28 23:23:11 UTC
From: <louis.wilen@...>
Topic: 48646 Message: 48646

My TS-530S hasn't had it's neutralization checked since I bought it brand new in 1982. Although it's 32 years old, it's had only about 14 years of moderate and careful use. It's been tuned up carefully and loaded it into a near 50 ohm load as far as I can remember. The rig is works as well as the day that I bought it.

Everything that I've read says that once the finals are neutralized, they don't ever need to be neutralized again (until they are changed.) But I figured what the heck, it's been 32 years, why not check?

So I took my (recently calibrated by Fluke) Fluke 179 DVM and Fluke 85RF probe and an "accessible" dummy load (a PL-259 with a 51 ohm resistor mounted in it) and followed the instructions in the TS-530S user manual for neutralization.

To my surprise, the initial output voltage was 35 mV. (I expected around 10 mV.)

Neutralization was easily accomplished, and the final DVM reading was 2.4 mV.

The rig still works fine after this "unnecessary" neutralization.

1. Since the capacitance of tubes (supposedly) doesn't change over time, why was I able to neutralize to a lower voltage level?

2. Is it likely that the rig was poorly neutralized at the factory?

3. Does the capacitance of tubes typically change over very long periods of time and over many hours of use?

4. Might some other component besides the tubes have changed value over time, which then caused the neutralization to be affected? If so, what component might that be?

Thanks for any replies.

48647. Kenwood Hyrbrid Net Update (April 28, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-29 00:44:07 UTC
From: Mark Gilger
Topic: 48647 Message: 48647

Dayton Hamvention Kenwood Legacy Forum:
This year will be the first year for the Kenwood
Hybrid Legacy Forum to be held at the Dayton
Hamvention. The forum will be Sunday May 18th.,
room #2, 10:30 □ 11:30. The following preliminary agenda has been proposed:

```
* History of the legacy products.
* Resource help with parts, documentation, etc..
* SDR integration into the legacy line.
* Rewinding a TS-830 L41 coil.
* Tips & Hints.
* Questions and Answer Technical Session
We hope to see you there.
```

```
Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net
```

```
Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

```
The net was run by me, WB0IQK. There were
17stations checking in under poor band
conditions. There were 4 new stations checking
in, KK4PWE, N2RTD, AC8FJ, and KD8VUX. We had the
following number of radios checking in.
```

```
1 running TS-520(x)
4 running TS-530(x)
3 running TS-820(x)
1 running TS-830S
```

```
I was running my TS-940S with L4B amp.
```

```
There was no Sunday 20 meter net. All of the net
controls could not do the net.
```

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 80, Sunday☐s total = 85
March 2014, Saturday☐s net total = 82, Sunday☐s total = 73
April 2014, Saturday☐s net total = 64, Sunday☐s total =43 (Month to date)

Dave,

If the frequency counter has connections (PL-259 or BNC) for the "antenna" & "transmitter" is should work fine...but...it will most likely show the frequency only when transmitting. Check the specs..if available..to make sure the sampling sensor can handle the 100W output of your rig.

Les:

This is why we need to hear it. It is not a "hum". Electronic techs think of a "hum" at a very low audio frequency. Normally at 120hz and this is due to fact that the rig is powered by the 60hz 120VAC line and the power supply rectifies this AC and filters it with electrolytic capacitors and the ripple content is at 120hz and as the capacitors age this "hum" becomes more noticeable and can be very excessive. Poor grounding can also result in a HUM. The HUM is resident on the 9vdc, 14vdc, 12vdc etc bus lines that supply the various circuits. If the HV filter caps get leaky the HUM can be heard on your transmit audio.

Anyway I would say you do not have a HUM on any of the supply voltages. It sounds to me like you have Feedback that is causing oscillation at a much higher audio frequency than 120 hz. With the mic disconnected it would appear this is not audio feedback thru that chain.

It almost sounds to me like your "detector" for Remote VFO calibration is not being cut off? This has to do with VFB/VFC and diodes D3 and D4 on the AF board. It sounds like to me that Audio pre-amp Q2 on the AF board is not being cut off when you flip to Send. RL on Pin 1 of AF-3 accomplishes this.

I think I would try cleaning Molex connector AF-3 on the Audio/AVR board as a first step. Then we can measure some voltages at AF-3 including RL if cleaning doesnt resolve the problem.

I have never seen this before so have to think about it some more. Perhaps someone else has seen it and can jump in and help you.

You need a steady carrier on for a regular counter to read a freq. If you are a SSB operator it would not be able to read the freq. Alternately you could couple it to the VFO but it would read the 5 MHz freq and not the on-air freq.

48654. Kenwood R-820 Receiver For Sale

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-04-29 16:04:39 UTC
From: <raysdz@...>
Topic: 48654 Message: 48654

I have a very nice R-820 receiver for sale. The R820 is in great shape both cosmetically and electrically. No visible wear on both the covers or front panel. The only need is the analog tuning dial lamp needs replaced. I could always read the dial OK as is and felt no need to replace till I really needed to open her up. Front panel is flawless, dial lenses are clear and the digital readout is bright.

The receiver has the optional filters installed. I also have an unused kit which allows the R-820 to be mated to a TS-820 transceiver.

Manual included. A real hard to find receiver and this one plays and looks great too. I can supply pictures on request.

Asking $800 + S/H US Only

Thanks for reading.

Topic: 48649 Message: 48655

*For sale: Near flawless Kenwood TS-530Swith Inrad filters and many other upgrades.
*

*This radio has been restored to better than new condition.
*

S/N 202XXXX

I bought this superb radio about a year ago in inoperative condition. It was far from a basket case, however.According to its previous owner, this beautiful Kenwood hybrid had been used for a few weeks when new, then repacked into its original boxes (which you'll get) and stored away for decades.When I got it , it looked essentially brand new. The reason it didn't work was the fact that the band switch, other switches, pots and connectors had lain idle for many years.A thorough cleaning of all affected components, however, brought the radio to life -- flawlessly.

I then went to work upgrading this 530 to prevent future problems and increase its already superb performance.

For enhanced performance, I:

?Installed a new Inrad 2.8 KHz SSB filter

?Installed a new Inrad 400 Hz CW filter

?Installed a Kenwood 1.8 KHz SSN / CW filter

So, the radio now transmits and receives SSB with a beautiful sounding 2.8 KHz IF bandwidth. Selecting "Narrow" position on the mode switch yields a 1.8 KHz receive bandwidth in SSB. Normal CW receive bandwidth is now 1.8 KHz and the "Narrow" selection cuts it down to a discrete 400 Hz.Gorgeous!

As preventative maintenance, I:

?Installed new HV components (HV electrolytics and final amp cage parts)

?Installed HV protection mod (per Terry)

?Replaced cathode and screen resistors

?Replaced nylon band switch coupler with brass component from Ken, K4EAA

?Replaced RL-1 on AF Board with new component from Ken, K4EAA

?Rebuilt band switch using wire jumpers to prevent "corroded rivet syndrome"

For looks, I,

?Removed and cleaned front panel and knobs

?Replaced cabinet hardware with stainless steel screws

And, for good measure, I:

?Replaced final and driver tubes

The radio was then aligned by a top tech to factory specs (including neutralization of new finals)

As you can imagine, the radio now looks fantastic and performs perfectly on all bands (100+ watts @ a conservative 225 mAwith beautiful transmit and receive audio).

I am asking $695.00 for this radio (includes shipping in its ORIGINAL BOXES to the lower 48 states). That may seem high for a TS-530S, but the new Inrad filters alone represent $250 of that price.Plus, this radio is a completely trouble --free and cosmetically pristine example.

Payment ($695.00, shipping included) to Pay Pal is preferred, please. If you are unhappy with the radio (I can't imagine that, but..) I will accept a return for refund within 14 days.

Photos are available. Please email me at crgrbrts@...

Many thanks and 73,

Craig

Dave,

I would not waste time using that counter. The counter you are considering using will not display the frequency in receive and since sideband has carrier with audio present only during transmit, the counter will more than likely display zero or be blank during receive.

My advice is if you want a digital frequency display for your TS-520 then I would look for and purchase the DG-5 that's designed to work with the TS-520 in receive and transmit.

Les:

I wonder if what you are hearing is your side tone oscillator? I did have a 820 rig long time ago with shorted D19 in the RC network path and oscillator then gets feedback it needs to oscillate.

Try adjusting VR-3 (white trimmer pot) on AF/AVR board to see if you can effect the volume level. If you can then you know it is side tone signal

Also, what test gear do you have? Can you measure the level and frequency of the signal at VFB at Conn AF-3? It should be approx 200mv of 5Mhz VFO signal. (5.300mhz with VFO at 200). The more I think about it it is unlikely problem is coming in on the VFB line.

Louis

I did not see a response.

1. Think about what you are doing and the significance of 35mv versus 2.4mv null. Not sure how you could have had any expectation for a particular level unless comparing to other TS530S rigs that you have neutralized? The minute you touch the Plate Tune capacitor or the VFO at your "perfect" null it will change. When you got that 2.4 mv null did you then rock the Plate Tune capacitor back and forth to obtain another peak in RF voltage? If not, then you dont have "perfect" neutralization. You can always get it a little better null by peaking the RF voltage after each null with the Plate tune capacitor. Can do this two or three times until reach point of diminishing returns. However, it is really a waste of time. As noted the moment you move VFO from 28.8mhz or whatever frequency that you neutralize at the RF voltage will start back up.

2. The factory uses test jigs and employs production workers to do adjustments like this and I doubt they had any RF voltage level in mind just a "go-no-go" null using the easiest detector for a non-technical person. I doubt the factory did a poor job just not as meticulous as you were trying to do and certainly not measuring to 0.10 mv.

3. The tube data sheets (depending on manufacturer) shows a maximum of 0.22pf capacitance between the control grid and the plate. That is a very very small amount of capacitance and notice that it is a maximum value which infers there will be a range. The capacitor is formed from the metal grid winding and the metal plate and the vacuum dielectric. I suppose over time and many heat and cool cycles that the grid wires could sag a little and perhaps move closer or further from the plate and the inter-electrode capacitance could change ever so slightly.

4. Neutralization is only good for the band you are doing it on and most effective at the frequency you are doing it on. 10 meters is where it should be done as the Xc of 0.22pf is lowest there and the most rf energy will be coupled back from the plate circuit to the grid circuit. Xc = 159 x 10 to the -3 / FC. Xc = 25,119 ohms @ 28.8mhz and Xc = 195,522 ohms @ 3.7mhz. So very easy to see why tubes wont take off at 3.7mhz. Actually I have never seen them take off on 10 meters and I see some that have a heck of a lot more than 35mv at null. The fact that you can install new tubes and load to full output at 10 meters in preparation for neutralization without risk of damaging your finals says something to you. Some fellow are so nervous they first neutalize on 21mhz before trying to load on 10 meters and then neutralize.

5. I would not worry about any other components causing the null to be at 35mv versus 2.4mv. You could have run for a 1000 years at the 35mv null level without the tubes taking off. I assume that the neutralizing capacitor was stiff to turn? If so, this is by design so it does not float off its value from moving the rig around. If it was very easy to turn it needs to be tightened.

I like the fact that you are in to measuring but just have to realize there are tolerances and what the measurements are telling you. Kenwood has to give us specs and tolerances for

alignments otherwise some folks might think 20% for every parameter is good enough. Another example would be your regulated 9vdc and 3.2vdc RF-1 voltages. KW says to set them to within +/- 0.05vdc. Is it really necessary to spend inordinate amount of time doing this? Of course not, but setting them both there ensures that the rig will operate to design with typical line voltage variations, ambient temperature, operating temperatures, and component tolerances.

Wonder how the factory production workers set these two voltages on the line before the days of DMMs?

Terry K9TW

Hi,

The Spectronics DFD/K or rebranded Henry DFD/K will also work with the 520 and 820 radios. Early models had nixie tubes, real retro look, then large red led were used.

They turn up on ebay often, just keep a saved search.

There was a similar model for Yaesu radios too.

48663. TS830 Mode Switch

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-05-01 12:23:55 UTC
From: <kf4ofi@...>
Topic: 48663 Message: 48663

Guys I need some help. I had to make a shade tree repair to my 830. The threaded part of the mode switch was broken and I could not tighten the switch to the case of the radio. My only option, with out finding a replacement switch, was a little epoxy on the front of the switch. It works fine, stays put now. The problem is when I had the switch pulled up to apply the glue, I pulled a little wire loose. This wire is a white wire with a yellow stripe that attaches to connector #4 on the IF board. For the life of me, I cannot find where this wire came from. The radio now has no dirve and will not load up.

Does anyone have an 830 in pieces that they can look at to see where this wire attaches so that I can finish this repair. It may go to the mode switch, it may go somewhere else, but it was laying right beside the mode switch.

Some info or a pic would be greatly appreciated.

Thanks
Curt KF4OFI

Test gear only amounts to a signal gernerator, a digital voltmeter, and a home brewed RF probe, all of which is normally used for refurbing some vintage AM stuff. I don't think my knowledge will up to the task either.

I do think that I may have found the culprit in the situation though.... yes - that great counter assembly! If I disconnect the counter assembly, everthing (except the digital display) works just fine. One of the boards (don't quote me, I think it was in #X54-1160-00) in the assembly has a small hairline crack that I need to address. I don't know if my skill is up to the task. But, I do know that with the assembly disconnected, the feedback problem is gone completely. I have done all the hole-through platin fixes on the board (actually, they looked to be all done already - I did add a small wire through all the holes though). Currently, the counter works flawlessly, which I guess is a little subjective to the new issue I am having - so yes, in reality, I guess it does still have a problem.

Question - can I just live with it like it is? The feedback on xmit does not occur unless I have the AF gain set too high anyway. If I do attempt the repair on the board, I'd like to have a spare board handy before I start - Murphy has been know to visit around here on occassion.

Thank you so much for the time and thought you put into helping me with this.

Les

I and others following this would really appreciate knowing exactly what board you unplugged and if the rig still transmits when you flip to send with this board unplugged and it does so without the 1000hz tone when you advance the AF gain pot.

If this is true would like to try to understand why.

There are two boards

Counter Mixer Unit X54-1150
Counter Unit X54-1160

If it is the 1160 board then there are no outputs other than to the 1150 board. Would be good to know for sure if it is the 1160 board so we can try to figure out what is going on. Perhaps something coming back on the 5vdc regulated line?

Not clear how that results in the tone you are hearing. Perhaps it involves the 5vdc AVR board and feedback to the 14vdc rail? Might be bad decoupling capacitors?

An O-scope on the 5 vdc and 14 vdc inputs to the Counter Assembly and to the AF/AVR board would be very interesting to look at.

You might try unplugging the molex connector to the 5vdc AVR board and see if it stops the tone. The regulator is top side near the black power transformer. Very easy to unplug the molex connector to it. If that stops the Tone I would ask Bob if he has a 5vdc AVR unit and replace it along with your cracked Counter Unit board.

Always a good thing when we can bring closure to these unique problems so we can all learn from it.

Les

Looking at the Counter Unit board I do see some decoupling caps on the 5vdc rail on the board (100 uf and .047uf combo) so if the crack is just right these caps may not be shunted from the rail to the ground plane.

If you have some caps in your junk box could try paralleling up several and hanging on the 5vdc molex connector pin on the Counter Mixer board and on the 14vdc to the board.

You could also go to the AF/AVR board and pull Molex conn AF-1 and release the 14vdc lead at Pin 3 and using dc bench supply or 12 vdc battery (couple of Dollar store lantern batteries) to feed the board and see if tone is gone. This would prove it is coming in on the 14vdc line.

If you are looking for something new that is literally plug and play, check out the Electronics Specialty Products' DD-103. It has a blue backlit LCD display, and a cable that plugs into the external VFO port. The cable is an additional 20 bucks. You do have to do a simple and quick fine-tune once you install it, but that's it. Turns on and off with the rig's power. I bought one several months ago, and it works very well.

I unplugged the topside connector on the entire assembly for the counter unit. From the get go with the digital display, I was under the impression that it is "not needed" for proper radio operations - it just displays the frequency. Knowing that (or beleiving that), as that is the only unit I am aware of that has ever received any kind of service, I unplugged it to see what would happen. When the feedback like symptom went away with this unplugged, I looked a little further. That is when I noted the very small hairline crack on the board I stated in the previous message.

Interesting though, prior to the feedback like symptom, the display had the "9" problem. Since the feedback situation has arisen, the digital display has been flawless. If I had to pick which problem to have and put up with, I pick the current issue of dealing with the feedback like issue.

The molex connector you refer to - I'll disconnect that this evening and see what happens. Will the radio funtion adequately with that disconnected?

I'll get another youtube vid together as soon as I can. It probably will not be until tomorrow evening to show the cracked board. Thinking about it, I can make a vid tonight with the counter assembly disconnected on the top side - that much will be simple.

I hope you realize how much I appreciate your assistance with this. I really get the impression that you are truly concerned about this radio.

THANKS!!

Check that, the last message. This morning, right before I left for work, I took the top cover off and pulled the accessible connector to the counter unit. The feedback (I'm going to refer to it from here on out as "feedback" lacking any knowledge or experience to call it anything different) persisted with this top connector unplugged. I swear - the other day when I tested, it went away. I do recall though, the top AND bottom covers were off that day, so most likely, I had the bottom connector removed. Perhaps something else, un-noticed caused the feedback to disappear. Maybe both connectors need to be removed. Whatever it was, there was no feedback the other day - I could not make the rig exhibit any problem then....

I will double check this this evening and post results at that time. I will reconnect everything and make the feedback happen, I will disconnect what I beleive is causing the issue and verify.

Thanks to Terry for the suggestions. In further study of the schematics I was able to determine that the signal cable which links the WWV switch to the RF board via X Verter was missing. We finally have receive which seems more sensitive than my FT-757! On to transmit. Following the set up in the manual I get 60mA on plate idling current as expected. Beyond this step there is no deflection on the ALC. HV shows 900 V. SG switch is up. I swapped out the 12BY7A with no change. I am hoping you folks might offer some suggestions along with a bit of reasoning behind them. I really want to gain more understanding of this rather than just swap parts. Thanks to all for this and all the other great info here! Rig is TS-520

You have been most helpful. I feel bad - it seems like every time I get on here to give you some info, I have to change it.

I took the top and bottom =covers off and for the life of me, I could not reproduce the lack of feedback - disconnected the top counter connector = feedback. Disconnected the bottom counter connector = feedback. Disconnected both = feedback. I know earlier this week, I had an instance where I had no feedback.

Then I noticed this relay -- (this is a link to the pic hosted on my website on my server)

http://linuxweb.homelinux.com/relay.jpg http://linuxweb.homelinux.com/relay.jpg

I keyed the mic (heater off), AF Gain high enough to get "feedback". I gave this relay a knock with a pencil while still keying the mic = feedback changed!! I turned off the rig, took out the relay, popped off the clear plastic cover, gave it a squirt of cleaner. Now, no feedback unless I turn up the gain all the way to 9+.

Well, wait a minute... I just check. The feedback has returned back at the level as before - around 4 on the AF gain. I am pretty sure the culprit is this relay though. Is this relay the same as;

http://www.hybridrestore.com/parts/ http://www.hybridrestore.com/parts/ (scroll down to the relay - it's about half way down the page)

If you think this is my problem, the part will be ordered as soon as I hear from you. BTW - read the entire bit of info about this relay - this guys test is to tap on the relay while using the radio - yep, that's what I did.

THANKS!!!

Leonard has been patiently suffering with my ham-handed assistance to get some of his original problems straightened up. We've been working on it, running through the operator's manual, and the latest and last thing was a simple coil pack alignment, which he said went smoothly.

Then he put in a new driver and finals, neutralized the finals which task he described as quite smooth and easy. No problems at all with the neutralization....

And then he went on to tune up with a dummy load, and THAT'S when all heck broke loose, to use the vernacular.

The chart below is from his message to me, when I asked him for readings on the plate currents per band along with the power output readings. The HV readings were all about the same, nominal, about 800V or so.

> -------- Original Message --------
> I'm now going to go through all the bands again and document the IP on each band.

>
> The same thing on 80, not nearly as bad.

One assumption I'm making (should have asked him, just now got the notion, yes, I can be slow sometimes) the settings he is using for the tune-up and for the measurements.

I'm assuming the tune position for balancing the tank and CW for the power measurements. Also how is he measuring the power, with the S meter or an outboard meter on the dummy load? I should have asked for

certain, and will shortly do so. Now, this has truly got me up a stump. I have this feeling that the answer is right in my face but I can't see it. Dagnabbit. I hate being stupid.

Why is the HIGH FREQ way over normal, at nominal drive levels and plate voltages, and the "easy" bands (40, 80) so low?

15 is about right for output, but the rest of this has me baffled.

Backing the equations out, you get a 600V 2K ohm load circuit at 10M but the 160 M circuit comes out to about 15 V and only 60 ohms. That is seriously UN-good. There is a lot of power going somewhere instead of out the antenna, and it can't be good, wherever it is going.

I'm wondering how capacitance and coil Q enough to get that kind of output on 10 meters got into this circuit? What sort of shorted coil along with some kind of parasitic capacitance would raise the circuit quality factor enough to get 130 W out of there? The same fault would account for progressively lower power on the other bands, so it's all one problem. THAT much I can get.

I just know from reading this forum (thanks again, Terry, for explaining that design compromise for ten meters) that it's hard enough to get 80 watts output with the low Q of the coil that had to be used in the 10 meter circuit, to balance/resonate with the tube capacitance and the little bit of parasitics in the rest of the circuit components, and STILL be able to use the same tuning capacitor to cover the complete band edge to edge-plus. (The original engineer must have been some kind of high-forehead bulging cranium. Designing this kind of complexity and inter-action component to component is SO far beyond me.)

Bad connection on the tuning capacitor frame? Shorted tuning coil somewhere in the finals? I am somewhat baffled, but I'm still hunting. (Not being in the same state as the busted box ain't helping, either. Especially not at MY level of "expertise." I almost laugh using that term, even in quotes.)

What I DO know is that something is SERIOUSLY out of tune somewhere, and I'm sort of at a loss where to even start. Low output on the higher frequencies I can deal with. Low output on low frequencies, HIGH output on high freqs, just makes me scratch my head and wonder "HOW the heck?"

Leonard, being the patient sort, is willing to wait until I beat my head into a pulp and get a brain-storm and figure this out. I however am not so sanguine about me getting that brain-storm before the pulp all drips out onto the floor. Plus, he might actually want his rig back and working one day....

Just a clue where to start will be much appreciated. I'm favouring something on the coil pack, or the main tuning capacitor, for some reason. My brain is kind of nagging me in that direction, which likely

means I'm completely on the wrong track.

Address any replies to either Leonard / WV3P, or to me, and we will continue to work this out together. I personally don't want to let this go, because quite frankly, it's kind of an interesting problem to me. (Whatever it turns out to be, we'll be sure to post it so someone else can start further along than "square one" like I am.)

If it's one of those "forehead slap" "Duh!" kind of answers in the end, that would be even better, since that kind of embarrassment means I won't likely ever forget it. (And the fix is easy for Leonard.)

Ideas? Please and thanks in advance?

Did you take the RF board out of the radio????????????????..... If so, did you ,perhaps, get the bandswitch shaft 180 degrees out of sync with the switch in the Final section????????? I did that and it gave me the whacked out readings that you got as to RF output....
Just a thought but it is worth the question....

Ron, someone asked if I cleaned the band switch. The answer to that is yes, I used DeOxit, but maybe I try it again. Can't hurt! I appreciate everyone's reply. When I first got the radio it only half worked on receive. I completely re-capped the radio, and removed the VFO for a good cleaning. I've also repaired the broken trimmer TC1 on the VFO which now works great. Receive appears to be working as it should. The radio has been re-tubed with almost new tubes that were checked on my old Hickok tester just to be sure, and I've performed the alignment per the manual. After putting in the new tubes I used my Scope to neutralize the tubes. That actually went very well. At that point I thought I was done until I checked the output. Did you have a chance to look at the chart I sent to Wes? I documented the Ip & Wattage on each band. 10, 15, & 20 appear to be fine. It's 160, 80, & 40 that have the problems, although 160 & 80 are the worst.

Thank you for your input.

Leonard/wv3p

48686. Kenwood Hybrid Net Update (May 4, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-05-04 21:06:59 UTC
From: Mark Gilger
Topic: 48686 Message: 48686

Dayton Hamvention Kenwood Legacy Forum:
This year will be the first year for the Kenwood
Hybrid Legacy Forum to be held at the Dayton
Hamvention. The forum will be Sunday May 18th.,
room #2, 10:30 □ 11:30. The following preliminary agenda has been proposed:

```
* History of the legacy products.
* Resource help with parts, documentation, etc..
* SDR integration into the legacy line.
* Rewinding a TS-830 L41 coil.
* Tips & Hints.
* Questions and Answer Technical Session
We hope to see you there.
```

```
Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net
```

```
Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

```
Jimmy, WB2KNR ran the Saturday net. There were
10stations checking in under good band
conditions. We had the following number of radios checking in.

1 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
2 running TS-830S

Jimmy was running his TS-520.

The Sunday net was run by me, WB0IQK. There were
9 stations checking in under poor band
conditions. There was 1 new check in, KD0VNQ. We
had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
```

1 running TS-830S

I was running my TS-820s twins. The TS-820s & R-820.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 82, Sunday□s total = 73
April 2014, Saturday□s net total = 64, Sunday□s total =43
May 2014, Saturday□s net total = 10, Sunday□s total = 9 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Sounds like not biasing off the receiver front end devices in TX mode. Could have you take some measurements at RF-2 on RF board and try temporarily grounding RLK but best to just clean the relay contacts or replace the relay.

Clean it by wetting strips of copy paper with de-oxit and pulling the strips thru all the contacts. Will see black streaks on the paper. Can also swap this relay with the Ant TR relay as they are the same.

Good idea to buy a spare relay while they are still available.

Hello OM(en),

I'm Jeff KD9AGN Tech. I got my ticket just this Jan. Working on getting my General next month. When I passed my Tech exam I treated myself to a Kenwood TS520. I know these are reliable old war horses with a little TLC.
This rig has been receiving very well considering I only have a 10 meter wire dipole in the garage rafters. Jan was too cold to be out messing with antennas!!
Kenwoods always had superior front ends. But I have a problem with transmitting SSB. I can tune up on all bands CW and get a signal out of the radio into a dummy load. Obviously I only have SSB on 10 meters So I then switched to USB and keyed the mike. Nothing. Now what? I have a DVOM and a few hand tools. Then the light bulb came on!! Yes "The Light Bulb Dummy"!! A CRUMMY DUMMY of yesteryear. Sure enough, I send a nice (rather weak visually, probably worn out tubes) CW signal on all bands. So then I hooked up a rock mite qrp rig to the antenna, tuned my kenwood to 7030 and keyed up. Beautiful signal!
I really really suck at CW BTW!! Back to 10 meters with this discovery and when I key the mic and try to send my call and test Nada, nothing zero zilch.
Is this a common problem with these old tanks? If so what should I be looking at?
Jeff KD9AGN

Jeff,

Do you have the TS-520 operator's manual? Also did you perform the transmitter sideband bias pot adjustment (60ma), the normal transmitter tune up procedures and the mic gain setting for normal sideband (USB or LSB) operation as discussed in the 520 operator's manual?

Ya, Please check that..... When I screwed up that reinstall of the shaft(After a new coupler was installed) I had exactly the same situation...ALL my RF outputs were whacked out..... I installed the forward shaft correctly. (flip 180 degrees) and all was as it should be..... Simple fix IF that is the prob..... VERY good luck to you. These old Kenwoods are WORTH repairing..... I love my 830 AND the older 520s... I have 590 now but still turn to the 830 first for prowling the bands..... Love it!

Yes, yes yes!!
A chinese aftermarket mic that I bought from a ham on ebay. he emailed me to be positive of my rig, I think it is ok. Definately not optimal, but that is money better spent on getting the ol girl walking and talking again!

I cleaned the contacts on the relay this morning. So far, it seems to be running much, MUCH better. I won't say "problem solved", but I can certainly turn up the gain now, key the mic, and no "feedback" is heard.

I did order the relay. This one will probably work forever now, as I have a spare handy. But, that's good insurance.

Jeff,

If the microphone you purchased on eBay is an "Electret" then those microphones typically require a small DC voltage to be applied to the microphone for them to work. Also, most Electret microphones have a low impedance, approximately 2K ohms. The TS-520 has a high microphone impedance, 50K ohms. A 2K ohm impedance microphone can result in an impedance mismatch which can affect the transmit audio. Also, of the microphone is in fact an Electret that requires a DC voltage and that DC voltage is not applied to the microphone then there will be zero audio in USB or LSB transmit regardless of the MIC gain setting because there will be "no audio output" from the microphone.

Can you provide the eBay ad ID number? All eBay ads have an ID number, found to the right of the "Items Specific" section and just below the "Print | Report Item" links. If you could see and read about the microphone you purchased it would make it easier for us to help you.

I recommend you find a high impedance microphone such as a Kenwood MC-50 that's designed to work with the TS-520. A non-amplified D-104 will also work. The MC-50 is a dual impedance microphone. The impedance is determined by the cable that's plugged into the rear of the microphone, see the MC-50 manual for further details. If you use a non-amplifier D-104, the wiring diagram is located on the plate on the bottom of the microphone stand. Remove the 3 screws holding the plate to the bottom of the stand and turn the plate over. The microphone ground and the PTT ground must be separate which requires 4 wires in the microphone cable. See the 520 operator's manual for microphone plug wiring details.

Have you tried transmitting SSB into the dummy load? Do you see any deflection on the meter, set to RF?

Check your MIC GAIN control, or in fact just turn it all the way up for now. You can set it properly once you work out what's going on.

Don't worry about the output valves. They don't really fail unless they have beeen massively abused. If they haven't been utterly roasted until the cathode is stripped bare, then even a completely worn out and tired set of valves will still work (probably get you about 75W out, too).

It's quite possible the microphone Jeff is attempting to use could simply not be producing any audio output to the 520's microphone preamp/speech amplifier. Therefore, I think Jeff needs to provide the eBay ad ID number so we can see what microphone he is attempting to use.

I am working on a TS-830S that receives fine but does not transmit -- no drive and, obviously, no output.

Here's a clue: the meter -- including the S-meter - does not function.

Any ideas?

73,

Craig

Wes:

1. In this state I would suggest keeping the key down testing to short intervals to rest the finals and the driver tube. 2. Max plate current for a TS520S is 200ma so I would back the Car Level down a little below this 250ma to 260ma Ip level while doing these key down adjustments of the Plate Load and Plate Tune capacitors.

3. Where does the Plate current dip occur at on any and all bands (including those that you think are close to normal) with the VFO at approx mid range (best to test at 200 to 250 on the VFO so peak drive occurs at approx 1200). If the dip is occurring at odd positions of the tank cap pointer then usually only two problems A. Bad fixed padder caps or wrong ones being switched in and B. Wrong tank coil tap is being selected.

Do the Ip dips occur very close to the white band specific markings on the arc above the Red pointer?

4. Lastly make sure the adjustment nut on back of the Plate Load cap hasnt backed off and allowing the rotor to move back and forth axially. This can cause the plates to short.

Load does not have to be "going" anywhere in the sense it is leaving the rig. Of course it is being dissipated. The final tubes supply RF Line current to the tank circuit. If tank is off resonance then there will be high internal RF Circ current in the tank and the ohmic series R in the tank is dissipating that current.

Wes/Les:

One other possibility that I forgot to mention and that is the couplers for the Plate Load and Plate Tune caps could have loosened up on their respective shafts and are slipping. Not likely but easy thing to check and eliminate.

Hello group,

I just (re)joined the group after I have broken my beloved and trusted TS-820. Yesterday I tried to make a PSK31 QSO and the rig tuned up OK. But when I tried to transmit with my new computer I didn't pay enough attention to the audio level resulting in massive ALC reading on my rig. I of course put the radio in receive mode as quickly as I could (about 1 sec on TX), but damage seems to have struck anyways. After that escapade there is no power output indicated on my external SWR meter in any mode including Tune, and there is no IP reading when I flip the T/R switch. There is also no high voltage reading, which I realize is needed for the tubes to work. :-)

I haven't checked anything inside the rig yet, I don't want to make bad worse. Where do I begin my search?

Thanks for any advice!

Thanks, Ron,

Yes, I do have known good finals and driver tube. I'm going to have to take some measurements of voltage and see where it disappears. I'm just trying to isolate the area, given that the metering, including S-meter, has failed with the drive and power output (with the exception of the HV metering, which is normal -- 900 V with no load).

Thanks gentlemen, I getting somewhere. This is the microphone I'm using, http://www.ebay.com/itm/NOT- FOR-CB-Superstar-Microphone- DM-507-4-pin-wired-for-KENWOOD-TS-520-TS-820s-/ 221422819309 http://www.ebay.com/itm/NOT-FOR-CB-Superstar-Microphone-DM-507-4-pin-wired-for-KENWOOD-TS-520-TS-820s-/221422819309
Gordon, I tried again this morning following your suggestion. Nothing at first, then I thought why not? I fiddled with the Bias pot while transmitting. It lit the light bulb weakly but flickered up and down with my voice!! I found that if I'm jiggling the bias pot I get output.
Yes I know I need a better microphone. If time was money I would be rich, however That is not the case.
Eventually I'll get a better mic, an antenna analizer, swr/power meter. I can live without an amp.

Craig,
It is possible the radio has more than one problem. Do the heater filaments light in all tubes? I worked on an 830 several years ago where the solder seemed to have evaporated (sublimated) from the socket's heater pins. After I resoldered the tube socket, heater voltage was restored & the unit had full output.

48716. Ground and -65V on Key for TS530S - First post.

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-05-05 21:09:45 UTC
From: Gary Hughes
Topic: 48716 Message: 48716

Hello All,

My name is Gary, 2E0REV....
I am slowly getting to grips with my cherished TS530S, after getting an ATU230 I want to wire up and connect my Czech Morse Key. (only ever used on an oscillator... so far) to my radio
From what I have seen plate and load can be adjusted using the CW switch.
I also want to carry out some tests using the key to determine power outputs when tuning and to see what my out put valces are running at.

My two questions:

How do I wire my key so I do not get the polarity wrong and damage my radio?
From the manual there is a ground and -65V...
How can I tell if I have wired it correctly?

Secondly, I have picked up a mono jack plug from local electronics store, will it hanle the 65V potential difference.. or should a specialised plug be used?

I have also picked up a chassis socket so I can re-configure my oscillator to use the new jack plug instead of the banana plugs originally fitted.
This and other std test equipment I have can be used to test and verify any solution offered prior to connecting to my radio.

Any assistance or advice greatly appreciated, if there is a thread already please lt me know of the location.

I look forward to your replies.

73 2E0REV
Gary

Hey Jeff, congrats on getting Tech. I'm working on General, too. I also have a TS520,and had an issue similar to yours (tuned ok, output on CW, NOTHING on SSB). I found that the mic gain/compressor control had a little play in it, and when I wiggled it, the rig would have output. I used DeOxit to clean mine, and that seems to have cured it for now. Just a thought to add to your troubleshooting, it worked for me.

Gary,

The key you speak about using, a Czech Morse Key, appears to be an enclosed straight key, at least that's what I can get from the website I found that talks about the key and shows a picture of the key. I could be wrong but if the key is an enclosed straight key then it's nothing more than a SPST N.O. switch that is closed only when you press on the key with your fingers. Also if the key is a straight key then it doesn't matter how you wire the CW key mono plug. A simple mono plug will work AND handle the -65VDC CW keying voltage.

Running any digital mode that transmitts a constant carrier will overbheat and damage tubes in a hybrid rig, and in this case you may have blown out the cathode resistors in the final circuit.

Thanks Brett,
I think it is a dirty pot. Deoxit here we go. :) That's OK with me. This way I learn something!! I know I have to pull the VFO one of these days and clean the bearings and relube. I expected to work on this rig and chose this old tank because I can do my own work if I know what to do. Not getting on the air isn't quite the handicap I expected. I have a lot of listening time to several nets and many, many rag chews. I'm learning something new every day and having a blast doing it. Plus I'm learning my rig inside and out!! I was concerned about getting a suitable wire in the air and built a ZS6BKW 300 ohm twin lead fed dipole set up as an inverted V. It's supposed to work all bands on my 520 without a tuner. Well, I expect 75 meters will take a tuner, but thats not the end of the world. I'm going to find out.

In answer to the questions that in your response:

1. I expected that I'd get the voltage down to 10 mV, based on http://www.k4eaa.com/faq.htm http://www.k4eaa.com/faq.htm (How can I Neutralize my Finals?, point #6, "You should be able to get down to 10 millivolts or so."). Having read your explanation, I now realize that K4EAA was using the 10 mV figure as just a typical value, not a specific set point. And no, when I got that 2.4 mV null I did not rock the Plate Tune capacitor back and forth to obtain another peak in RF voltage. That didn't even occur to me, but now that you mention this (optional) "step", I understand better the principals behind neutralization, even though taking this extra step is, as you said, a waste of time.

2. Great explanation. This also clears things up.

3. Ibid.

4. Ibid.

5. The neutralizing capacitor screw was stiff to turn. Definitely designed to not turn accidentally.

Would you mind if I forward my question and your answer to K4EAA and suggest that he add it to his FAQ (with full credit to you, of course)? I think that it would be a worthwhile enhancement to the neutralization explanation in his FAQ.

Thanks Mike,

Your information ties in with my knowledge of the key and how it operates, knowing the jack is also able to handle the voltage is also good.
Thankyou for your reply, it give me confidence in connecting the key to my radio.

On a seperate thread, as a new user of the 530S are there any tune up sequences you would recommend ... that are not in the manual....?

Many thanks for your time.

73 Gary, 2E0REV.

Gary,

The key you speak about using, a Czech Morse Key, appears to be an enclosed straight key, at least that's what I can get from the website I found that talks about the key and shows a picture of the key. I could be wrong but if the key is an enclosed straight key then it's nothing more than a SPST N.O. switch that is closed only when you press on the key with your fingers. Also if the key is a straight key then it doesn't matter how you wire the CW key mono plug. A simple mono plug will work AND handle the -65VDC CW keying voltage.

Gary,

The only thing I can say is I recommend you thoroughly read the manual, paying attention to each control and what the control is for. If you have any questions about what you read in the manual, don't side step them, ask here so we can explain them for you. Too many hams today don't take the time to read the manual. Quite often some problems experienced by the operator are "operator error" because the operator didn't read the manual or they read it, didn't understand what the manual was telling them but they simply didn't ask for help/explanation!!

Do you have a 50 ohm dummy load that has a power rating of 200 watts or higher? If not then I recommend you purchase one. Start learning to tune up the 530 into a 50 ohm dummy load then switch the 530 to what ever antenna you will be using.

Make sure you check the 60ma idling current bias pot setting before you attempt any operation on any mode!

During TUNE mode DRIVE control adjustment with the meter switch set to ALC, ignore the ALC scale!! Adjust the DRIVE control for a peak meter "pointer" indication. If the meter pegs fully to the right simply rotate the CAR control so the meter pointer drops to 11 o'clock then continue adjusting the DRIVE control for a peak meter pointer indication. The only time the ALC scale comes into play is in USB or LSB mode operation.

If you do not have a watt meter then I recommend you purchase one. The watt meter should have a power rating of at least 200 watts or higher. You should always tune the 530 up into a 50 ohm load then switch to the antenna of your choice.

If the watt meter you are using is an average type understand the peak indication you will see during USB or LSB operation will be approximately 20 to 25 watts on peaks. This is normal and should not be an indication that you turn the MIC gain up so the power indication is higher. If you do that you will create splatter and make a lot of stations mad at you so do not fall into the trap many inexperienced hams tend to do and that is to turn the MIC gain up so the watt meter shows full output!! Understand that it's NOT how "LOUD" you sound at the receiving end but how "CLEAN" your transmit signal is with the MIC gain set properly!!!

Good luck and enjoy your 530.

Louis:

The only enhancement to Cold Neutralizing that I provided over what Ken has on his site is to re-peak the Pi-network Plate Tune and Plate Load capacitors after the first 2 or 3 null adjustments. The goal is to get the maximum RF output to occur as close as possible to the plate current dip.

I was trying to explain that there is no magic minimum feed thru RF voltage level specification. Kens 10mv is a level that from experience should be attainable. You proved that in your experience 2.5mv is attainable. In either case I wanted you to know since you had not re-peaked the tank circuit after reaching this null you had not accomplished a "perfect" neutralization and that in practice there is no reason to fixate on it as the moment you move that VFO and/or that bandswitch you wont have 2.5mv.

You can Goggle on Neutralization and Neutralization of Tetrodes and find numerous technical discussions. Eimac has an excellent Section 5 Bulletin if you are interested in learning more. Some of the best Ham discussions include the work that Tom Rauch W8JI and Peter Roberts G4DJB (Yaesu FT-101 Restoration site....I almost couldnt type the 'Y' word!) have on the subject. Toms will be more technical treatise and Peters is just a step by step procedure under his restoration page.

Just wanted you to have a better understanding of the what and why and the practical aspects of what you are doing when you neutralize.

With a Class AB1 rf amplifier in practice peak RF output and minimum plate current are not going to occur precisely at the same point. Have to understand resonance, anti-resonance, elliptical load lines etc to understand why this occurs and far too many key strokes required. This is one of the reasons why loading for max RF output within plate dissipation is much better than the old dip and load method.

You are free to send Ken anything you want. He doesnt need any tutorials from me and not likely he will be revising his website content based on any of my work. On most things he and I are in total agreement and on others we have differing opinions. We are friends and not in competition with each other. I like to think we complement each other for the most part.

Hello Mike,

Many thanks for your comprehensive mail.

Good news, my key now has a phono plug on it and is working well in the 530, I just need to get past any operator error and use the radio as it should be used.

I do not have a dummy load, that is my next aquisition, I may build one myself, there are plenty of schematics out there to choose from.

The ATU230 has a power meter, as well as all the switches to tune up on a dummy load, my HAM depth of knowledge and understanding is coming together exponentially at the moment.

You nailed the MIC gain scenario this was why I was keen to get a key connected to the radio.

Two questions have come to mind since connecting the key...

1)With the mode on switch CW, when the REC/SEND switch is in the REC position I can hear signals on the band, but only CW power goes out when the switch is in SEND...

Do I really need to switch between REC and SEND t send and recieve CW if I was working the key?

2) I can hear CW when mode is set to LSB on 40m.... but when I change to the CW mode the signal is lost and can not be resolved to CW signal that can be listened to, this has perpleaxed me, but today is the first time I have tried this.

Should this be the case?

As said earlier, I am on the steep learning curve for the 530 at present but enjoying the journey, this also leads back to reading the manual but not understanding it...

Again many thanks for your time.

Gary,

Question 1
You do NOT have to use the SEND switch to switch from receive to transmit and back again. For CW all you need to do is turn VOX "ON". This allows you to operate "Semi Break-in" where all you do is start sending CW in CW mode. The VOX circuit will control the transmitter. You will also hear your CW sending in the speaker, this is what is called a "Side tone" but you hear it in CW ONLY and ONLY when you are sending. When you stop sending the VOX DELAY times out and the 530 switches to receive automatically based on how you set the VOX DELAY. Set the VOX "DELAY" control so the transmitter remains keyed between the dits and dahs for a second or two. You will have to play with the VOX DELAY to get the delay set to the time period that you are comfortable with. This is covered in the 530 operator's manual.

Question 2
If you can hear CW and other signals in USB or LSB modes but when you switch to CW mode the receiver appears to be dead then more than likely the previous owner had the CW filter installed but removed the CW filters when he sold the radio but he did not put the CW/SSB filter jumpers back when no CW filter is installed. If you look on page 23 in the 530 operator's manual, Figure 5-2 "Filter Installation", jumper "A", with no CW filter installed, should be connected to "CW" not "SSN". Jumper "B" should be connected to "SSB" not "SSN". The jumpers are located on the upper left corner of the IF UNIT board. Remove the top cover of your 530, the IF UNIT board is on the "left" (front panel facing you). Look at the "A" and "B" jumpers in the upper left corner, if jumpers "A" and "B" are both connected to "SSN", move jumper "A" to "CW" and jumper "B" to "SSB". You will need to use a soldering pencil, 30 watts maximum, to move and solder the jumpers to the "CW" and "SSB" terminals on the IF UNIT board. This will allow you to operate and hear CW signals with the Mode switch set to CW.

If you feel you cannot perform the filter wiring/jumper changes I mentioned above then find a local ham who has the experience who can help you. Don't try to do this if you are unsure of yourself as you can damage the IF UNIT board.

Gary,
If you want to be able to work semi-break-in, where the radio switches automatically to Transmit mode when you press the key, switch to vox mode and set the VOX delay max Clockwise. If you release the key the radio switches back to receive in a second. You just leave the T/R switch in the Receive position.
On Tuesday, May 6, 2014 6:02 PM, Mike W5RKL <w5rkl@...> wrote:

Gary,

Question 1
You do NOT have to use the SEND switch to switch from receive to transmit and back again. For CW all you need to do is turn VOX "ON". This allows you to operate "Semi Break-in" where all you do is start sending CW in CW mode. The VOX circuit will control the transmitter. You will also hear your CW sending in the speaker, this is what is called a "Side tone" but you hear it in CW ONLY and ONLY when you are sending. they simply didn't ask for help/explanation!!
>
>Do you have a 50 ohm dummy load that has a power
rating of 200 watts or higher? If not then I
recommend you purchase one. Start learning to
tune up the 530 into a 50 ohm dummy load then
switch the 530 to what ever antenna you will be
using.
>
>Make sure you check the 60ma idling current bias
pot setting before you attempt any operation on
any mode!
>
>During TUNE mode DRIVE control adjustment with
the meter switch set to ALC, ignore the ALC
scale!! Adjust the DRIVE control for a peak
meter "pointer" indication. If the meter pegs
fully to the right simply rotate the CAR control
so the meter pointer drops to 11 o'clock then
continue adjusting the DRIVE control for a peak

meter pointer indication. The only time the ALC
scale comes into play is in USB or LSB mode
operation.
>
>If you do not have a watt meter then I recommend
you purchase one. The watt meter should have a
power rating of at least 200 watts or higher.
You should always tune the 530 up into a 50 ohm
load then switch to the antenna of your choice.
>
>If the watt meter you are using is an average
type understand the peak indication you will see
during USB or LSB operation will be
approximately 20 to 25 watts on peaks. This is
normal and should not be an indication that you
turn the MIC gain up so the power indication is
higher. If you do that you will create splatter
and make a lot of stations mad at you so do not
fall into the trap many inexperiencedÂ hams
tend to do and that is to turn the MIC gain up
so the watt meter shows full output!! Understand
that it's NOT how "LOUD" you sound at the
receiving end but how "CLEAN" your transmit
signal is with the MIC gain set properly!!!

Topic: 48698 Message: 48731

Today I successfully overcame the no drive/no ALC/no metering/no output problem on a TS-830S that I've been complaining about for the past couple of days.

The radio did not arrive with this malfunction. It landed on my bench with a couple of other problems.One was quite curious. Even though power output was normal (100 watts on all bands), the iP reading was quite low -- somewhere around 160 mA or lower at the highest reading. ALC metering was very low, too.

I learned later that a previous owner, suffering from meteriindications that were way too high, wired a "meter correction" resistor in series with the iPM line to the final amp board. This, of course, did not address the root problem, but merely disguised it. In fact, the resistor overcompensated, yielding the low metering results I was seeing. Before I discovered this, however, I took a step that led to unpleasant complications. Noting that the bias current appeared to be way too low, I re-set it to read the desired 60 mA.I was the suffer the consequences soon thereafter.

After adjusting the bias with no apparent results and then discovering the modification to the metering circuit, I replaced the cathode resistors R2-R5 on the Final Unit board as well as the screen resistors R7 and R8 on the same board.When I powered up the radio, the receiver worked fine, but the transmitter was now dead. I hastily rechecked my resistor installations but found nothing amiss. I explored Molex connectors and -- aha! (I thought) found two headers on the IF board that were "wiggly".I cleaned off their traces and resoldered them.While I had the underbelly of the board handy, I replaced the four screen and driver electrolytics C178-C181 and wired in one of Ken Kemski's nifty new RL-1 relay boards to replace the tired old relay.

Still nothing on transmit.

I revisited the original work on my Final Unit board but still found no evidence of foul play on my part.Then, something next door on the Rectifier board caught my eye. R11, the 470 ohm 1 watt screen resistor, looked a little odd.I had measured it with power off from the underside of the board earlier and it seemed okay. However, on close examination a hairline crack could be seen 'round its middle.With a slight tug the resistor disintegrated, falling into four pieces.

Replacement of R11 was quick and easy and cured all ills.Metering was now normal. Remembering that I had "corrected" the bias current earlier, I quickly re-set it to the now proper level as evidenced by my now accurate meter. A quick check of the radio showed 100 watts plus output

on all bands at a conservative 220 mA.

Since I had the covers off, I went ahead and replaced C22 and C24 (the big 'lytics) on the chassis and installed Terry's excellent Final Unit Cathode/Screen Grid Protection mod as published on Mark Gilger's (WB0IQK) terrific website.

Lesson learned: use some logic when troubleshooting. If I had reflected upon the fact that the metering was wildly inaccurate when the radio arrived, I would have realized that "correcting" the bias current setting was counterproductive, to say the least. In actuality, I had erroneously set the bias to about 200 mA, even though it read 60. This was not good.Perhaps this is what blew screen resistor on the Rectifier board.At any rate, that resistor should have been an early suspect. Replacing it as I installed the new resistors on the Final Unit board would have saved me the better part of a day chasing non-existent gremlins.

Craig

How would having no screen grid voltage cause you to have no S-meter indication in RX mode? I thought you reported that condition as well?

For ALC indication in Tune mode you need:
1. 6146 cathode emission -- heaters on
2. Normal operating bias voltage on the control grids (approx -60vdc)
3. Normal RF drive level (approx 45 rms rf volts) at the control grids to overcome the operating bias offset.

You do not need screen grid voltage on the 6146 finals for ALC indication in Tune Mode.

If R11 was open that means no 210A bus/rail voltage which means no screen grid voltage to the 12BY7A tube which means you had no RF drive output at plate of the Driver tube. Which means no RF drive at 6146 control grids.

When you reported no S meter in Rx mode and no ALC I was looking for a commonality and that is why I pointed you to Conn 10 on the AF board to make sure you had SM from the IF board and ALC bus was energized at 3.6vdc. If you had SM arriving at the board then I was hoping you would find bad contact on RL-1.

Have you resolved the no S-meter problem? Did installing Kens new relay resolve this problem?

Terry k9TW

48734. Re: [TS-520_820_530_830] Re: 830 - no output, no metering CURED!

Yahoo group: TS-520_820_530_830 (2014)

Topic: 48698 Message: 48734

Terry:

Yes, indeed, the reported S-meter problem has been resolved as well. I am guessing that the replacement of RL-1 solved that.

The one remaining unpleasantry has to do with the band switch. It is functioning perfectly well, but I would like to replace the original nylon shaft coupler, which is cracked. The problem is that a repair with epoxy cement (!) was made to it by a former owner or tech (the radio has two service labels affixed tot he rear panel. The coupler is essentially potted in cement and may prove darned near impossible to remove. The purist in me hates to leave it as is, however.

Thanks,

Craig

Topic: 48679 Message: 48735

Hello Terry, I'll look into that. Someone else here also asked me if I had the RF board out. I didn't be ut, he said there's a possibility that the shaft could've been put back in 180 out?

I never checked the output of this radio before I started working on it. I went right to the receiver since that was the most apparent problem when I turned it on. There are two areas that I"m going to check the next time I get up on the bench. I'll check the bandswitch and clean it again (DeOxit), and look at the Plate & Load caps that you mentioned. Something really crazy is going on here.

I might add that the rx is also poor on 40, and possibly non existent on 80 & 160. At least it seems that way. I can't be sure since the bands don't seem to be that great lately. I will say that I've never heard anything on 80 & 160, but I have heard signals on 40. 40 meters is where the power output starts going down. The problems seem to be related?

Maybe this bit of info will help?

I have following items for sale:

1. Heathkit PK-3 RF Probe. This is the 3 diode probe that can be safely used to measure the RF drive level at the 12BY7A Driver tube plate or at the 6146 Finals control grids. I would say it is cosmetic 7 to 8. A small dymo label that states "3 diodes" has been affixed to the aluminum barrel. I have tested it and it is the 3 diode probe. $20 shipped.

2. Four NOS Aromat NF4EB-12V RL-1 Aux Relays (TS530 IF board and TS830 AF board). This is the replacement for the original and discontinued clear case Omron LZN4 relay that causes the intermittent Rx and Tx problems. All four shipped for $50.00 (CONUS) or $15.00 for one shipped.

Please contact me off List.

If you are receiving on 40 meters then it tells you that the "common" receive path from the SO-239 to the RF board is good (ant relay contacts, rf attenuator contacts etc).

Marker signal is not as good a test as calibrated RF sig gen but a good Marker signal on 160 and 80 tells you that the RF front end and the IF chain is good.

What kind of antenna are you using to copy on 160 and 80 meters?

A short length of random wire wont be very good. It is amazing how much difference a resonant antenna (like a half wave dipole) makes in the level of RF voltage available at the SO-239.

With rig on 3.5 mhz and VFO at 200 to 250 does the Drive Control peak close to 1200 position?

With the screen voltage off, and a dummy load connected, what ALC levels do you get on each band? If they are ok, then the problem is in the finals area.

If its the finals area, check the plate blocking cap and plate choke bypass cap. These are known problem areas.

Terry, the antenna is a Hygain 18avt vertical. It's not set-up for 160 meters so I can't really test the receive on that band. I've assumed that I should be able to hear something on that band even though the antenna is not actually for that band. On 80 I've never really heard anything, even though my ts-2000 is picking up stations at the house. The ts-2000 is on a different antenna (Gap), but it is a vertical. Granted this is a very rough comparison, but it's all I have to work with at the moment. Some of weakness I attribute to the radio could actually be with the antenna, but without further testing I can't really be sure.

When I get up to the Pole Barn I'll give you an update on the Drive Control.

Hi all,
I have a fairly new-to-me 520S. After getting my D-104 wired properly, I was transmitting an excellent signal and happy as can be. Then one day my contact was having a hard time hearing me. I saw on the meter that the strength was down to about 20%. I thought the mic was giving me trouble again. The next day, output was nothing at all.

I got a new mic and got the same. I got an MC-50 yesterday and again the same thing. I have a copy of the manual and have (several times) run the "Normal Transceiver Calibration" in section 4.4 of the manual. It's running beautifully other than this issue. Help!

Larry,

Very possible you have a failing 12by7a driver or failing final amplifier tube(s).

Tune up rig as usual(dummy load please). Check plate current (Ip) during transmit(CW-key down) Falling plate current (Ip) usually indicates failing final tube(s).

  Falling drive level usually indicates failing driver tube.

  Check your HV(high voltage) using the front panel meter...a small drop of say 10% is OK...any big drop usually indicates weak/failing HV capacitors.

 Over what period of time does this happen?.....a couple of minutes??..20-30 minutes??

There could be other causes...but these are the most common problems.

I doubt your microphone is the problem.

I agree with Joe.

When you tune up in TUNE mode, watch the ALC peak indication. If the peak ALC indication starts to drop off back towards zero after a few seconds then the driver tube is weak and should be replaced.

How hard would it be to put the KW Hybrid on the Gap?

A 1/4 wave trap vertical isnt going to be the best antenna, but should work reasonable well depending on how mounted and the radial system.

Is your 18AVT ground mounted or roof top mounted? Some folks mount on chain link fence.

What kind of radial system do you have?

Of course you are aware best to listen to 75/80 late evening.

With the Marker signal you describe on 80 and 160 and the good copy on 40 meters it is hard for me to believe you have a problem with the rig. My guess is that you would have approx 37 foot radials on 40 or shade longer depending on how you mounted it. If so, this probably accounts for the better performance on 40.

It has been years since I ran any verticals so I need to back away and let someone with more recent experience help you.

I can probably hook the rig up to the vertical, but I'm still confused as to why the rig puts out 4 watts into a 50 ohm dummy load? This might be a good way to see if I can duplicate the results on another antenna using my JFJ Versa Tuner V. I know for certain that tuner displays an accurate power out.

I'll let you know what my results were, and thank you for your help.

Rig putting out 4 watts has nothing to do with not hearing signals on 160 and 80. I thought Wes was working off the forum with you on the transmit problem? I hate to get involved. I will give couple of suggestions and then must move on.

Normally pretty easy to trouble shoot low RF output if you have the correct test gear. Lacking that can end up being a lot of guessing.

I think someone else already suggested that you confirm you have good RF drive level on all bands. I agree with that as easy to do and requires no test gear. You do that as follows:

1. Heaters on, SG switch off, CW mode, CAR Level Pot 1200, Drive Control at 1200, VFO at 200, Meter to ALC.

2. Flip to Send and peak the ALC indication with the Drive Control. If the meter goes FSD (full scale deflection) against the peg simply back the CAR level pot down until the meter indicates at 350ma. If you cannot get FSD at 1200 on CAR Level then advance it until you do. If you cannot get FSD then just peak it at whatever max level you can and record the amount of Car level it takes to do that. None of the scales mean anything. Just use the MA scale to report your findings.

3. Leave rig keyed for a couple of seconds to see if the full scale ALC indication slowly drifts down scale. It should not. If it does getting close to time to install another 12BY7A.

Repeat this test on each band and let the Driver tube rest for awhile between bands. The Driver tube runs Class A and plate current is close to max rating for the tube.

Make a chart that records the ALC indication vs the Car Level Pot position for each band and report back to us. Typically a good rig wont have to advance the CAR level pot beyond 1000 to 1100 with exception of perhaps 10 meters where may have to advance it to 1300 or so.

If you can get close to full scale ALC indication on all bands with CAR pot no more than approx 1200 then you know your Driver stage is good, you have proper operating -dc bias voltage at the control grids of the 6146 finals, and you have sufficient RF drive voltage swing at the control grids to overcome this dc offset and cause ua grid current to flow on positive peaks of the rf drive envelope which is what produces the ALC indication as the ALC amp reduces the ALC bus voltage and causes the meter to drive up scale.

If you have good RF drive to the Finals and low RF output then it is time to try another set of known good Final tubes. If RF output still low then it is time to take DC voltage readings on the Finals at the tube sockets.Screen grid voltage is very important.

If DC voltages are all to spec then need look inside the PA cage at blocking/coupling cap, RF bypass cap at base of RF Plate choke, and the RF plate choke (discolored windings).

In my shop I can measure the RF voltages across the Tank capacitor, across the Tank inductor, and across the Load capacitor. You wont be able to do that.

You may be able to do a good visual inspection inside the PA cage. Need to make sure that the couplers are not slipping on the Plate Tune and Plate Load caps (as I previously mentioned). Need to make sure the Plate Load capacitor shaft isnt slipping axially and shorting out movable and fixed plates. Need to look at the ANT TR Relay and clean the NO contacts.

All work inside the PA cage including visual inspection must be done with rig unplugged and the HV capacitors discharged.

This is enough to keep you busy.

This was over several days.
Good on day one.
On day 2, only about 20% power (consistently)
On day 3, no output at all. Totally flatlined.
I'll need some time to get a dummy load.

You're right Terry. This will give me plenty to chew on for awhile. Wes and I had been working on the transmit problem, but he graciously put a message up on the board for input. We're kind of at an road block at the moment and were looking for someone to give their advice.

I thank you for taking the time. The thing that puzzles me is the lack of power on the low bands, but not the higher frequency end. I'll check those things you mentioned.

This is why you need to do the RF drive test with the SG switch off.

You need to know if it is an RF drive problem. If you have low RF drive on those same bands then almost always bad bandswitch contacts as you are not switching in the Mixer and Drive parallel resonant circuits. Or switching them in with high series resistance.

Once you do this Drive test using your panel Meter and find low ALC indication the next step would be to use an RF probe and VTVM and run the TX Level Diagram to see where losing it at.

If your RF drive is good on all bands then can move on to the PA cage inspection items that I provided. If you have good RF output on the higher bands and not on the lower bands then that rules out a bad Ant TR relay contact.

This is a systematic process and at some point requires a modest amount of test gear.

Hello,

Thanks for the advice, but the resistors meassured 5.5 ohms and the choke seems OK. I have also meassured the 800V tap from the power transformer to over 750V AC (upper limit on my multimeter) and aproximately 450V DC over each high voltage capacitor, so the fault is somewhere between the capacitors and the tubes. Since I only have a low res schematic it's hard to follow all the traces, where should I continue my meassurements to find the fault?

Terry, my test equipment consists of a 100 Mhz Scope, various multimeters (one digital, and one analog), an rf probe that I built from a kit, and a signal generator. I still have a ways to go learning some of the test equipment. I just put the probe together and haven't had a chance to really use it. I have used the scope during the alignment process, but the frequency counter I have (Startek) has a lot to be desired. Still I probably have enough to perform some basic tests, or at least enough to get this radio working again. Fingers crossed.

I also re-capped the radio, but after talking to Wes he told me that's generally not a good idea as it can cause more problems then it fixes. I've been fortunate in that area. Everything seems to be ok. I really took my time doing it, and made sure the polarities were correct. It took me a few days to complete the task.

The radio is WAY better then it was when I first got it. The receiver didn't work at all when I first got it. I've had the VFO out 2 times so far so I could really get inside it to clean it properly. Now all the birdies have went away and I can actually hear stations. At this point I'm going to assume the receiver is working 100% and the only problem that I have with that is in the antenna. I'll address that later.

I've learned so much in the last two months working on the radio. I work on the radio when I have the time, but now I really would like to get it off the bench. Still, if there's one thing I've learned it's to be patient. I absolutely will do everything you mentioned and will ask questions when I'm not sure of something.

Terry, I'll get back to you once I've completed all the tests you mentioned. Thank you again for your input.

Terry, I'm ashamed to admit it. I thought I had the SG switch in the OFF position. It seems that I made a HUGE mistake. Now I've just made myself a whole lot more work. I unplugged the radio, and drained the caps (twice) and looked for something that's apparently smoked, or bulging. I can't smell anything. I guess I'm going to get schooled on this one.

Now I'm mad at myself for not double checking!!

I am apparently missing something here in your responses as I dont know what you are talking about.

I assume you are saying you were trying to do the Driver stage testing with the SG switch in the ON position. Is that correct?

If so with long and repeated key down periods (maybe some of it in an off resonance state) you could have hurt a Final tube. 6146 would be the most likely weak link in this scenario.

Also check the 5 ohm cathode meter shunt resistance to chassis ground. They can take a significant over current for a very long time. If you have no 900vdc at top of the large RF plate choke look at the small VHF plate choke at the base.

Be extremely careful measuring the 900vdc at top of the plate choke. Might want to connect your meter with rig down powered and then get hands away from the meter and test prods and clip leads and turn the rig on. Make sure the clip leads laying on the bench are in the clear.

If you now have no ALC indication in Tune mode with SG off and previously had it I would try another 12BY7A driver tube. As I previously stated you need three things for ALC indication:
1. Cathode emission from the 6146 finals (heaters on and good cathode resistors)
2. Operating bias at the control grids of the finals (approx -60vdc)
3. RF drive voltage swing at the control grids of the finals from plate circuit of the Driver Tube (approx 46rms volts or approx 130v P-P)

Again be very careful working in the PA cage, around the HV rectifier board, and the HV filter caps. Cant make any mistakes here as could be your last one. Must go slow and attention to detail.

Yes you have the test gear you need. I assume you have the 10x probes to go with the scope?

When time comes I can help you use it to take necessary measurements.

Some prefer to use the O-scope to take the RF voltage measurements and some prefer the meter and rf probe.

Here are some typical (approx) TX rf voltage levels @14.200 mhz

1. TIF input to the Transmit Mixer on the RF board measured at TP-2 = 0.25mv or 250mv rms or 700mv P-P

2. Transmit Mixer output on RF board measured at MD or TP-1 = 2.0volts rms or 5.8volts P-P

3. Plate of the Driver tube measured at DP or DRV = 58.0volts rms or 164volts P-P

CAUTION: Must use a 2 or 3 diode RF probe if not using RF millivolt meter or O-scope to take this measurement. This level of RF voltage will exceed the piv rating of the typical single diode probe and destroy the diode.

4. Control grids of the 6146 final tubes measured at tube socket Pin 5 = 46.0rms rf volts or 130 volts P-P.

Note: All readings taken after loading to approx 100 watts output into dummy load and then turning off SG switch.

Note: TIF signal is not band switch dependent and not your problem. Cannot measure it with your meter and RF probe must use your O-scope.

Terry, I was trying to check the ALC as per your last email. I had everything set up properly except for the SG switch. It was supposed to be OFF, and I mistakenly had it ON.

You wanted to put the meter in ALC and adjust the carrier to get a reading of 350 ma on the meter with the transmitter keyed. To make a long story short, after the rig was keyed for probably no more then 30 seconds or so the rig made some clicking sounds (relay?) and the lights flicked off/on about 3 times. After that the rig went dead. I immediately shut the rig off (too late), and went to the back to check the fuse. It was then that I discovered the SG switch was on, and not off like I thought. The fuse checked good, but now the the radio is completely dead. No power at all. I looked the boards to see if something looked burned and could see nothing. I also tried to use my nose which isn't the best to see if I could smell something, but again I couldn't detect anything out of the ordinary.

I hope this is a little clearer? Instead of finding the reason for low power on some of the bands, it looks like I'm now going to have to find the radio is dead before I can go on. To say that I was upset at my mistake is probably an understatement.

Just a final thought. I really didn't have the rig keyed for long. Maybe 20 to 30 seconds before the lights started blinking on and off. Actually the key down was probably closer to 20 seconds. I'm not sure if this is useful information or not?

Hopefully you have not lost the power transformer. If it suffers shorted windings I would think it would blow the 6 amp primary fuse, but perhaps not if an open winding.

I would check for a bad ON OFF switch and bad wiring at the 120vac line cord power plug connector at rear of rig. Of course must have a good 120 vac house receptacle.

Easy to measure the voltages at the power transformer to see if you have 120vac to the primary winding when you turn the front panel Power switch to the ON position.

Just be careful taking transformer voltages.

The voltages on the transformer secondary windings are labeled with the name of the supply and not the actual ac voltages that you will read. For example the " 800 " winding will read approx 340vac.

Too soon to panic. Could be something simple.

Remember I wasnt telling you that you should read 350ma of plate current. Meter has to be in ALC position and I was trying to tell you that you should be able to peak the Drive Control to get full scale deflection on the meter. That can be 350ma, or 10 on red HV scale or 40dB on S-meter scale. Just seeing if Driver stage is capable of FSD with approx no more than 1200 of Car Level on all bands. Make sure you read my previous step by step instructions and understand them and follow them literally.

Hello all again,

I recently picked up a PC 1 phone patch. The price was right and there is a chance that i might be doing some phone patching for a friend who will be maritime mobile.

After giving this unit a closer look, there is a mod that was done. There is an RCA jack mounted on the rear with a resistive voltage divider. 2 k from center pin, then an 8K to ground. from the divider, it goes down to a terminal board with a few caps and two 2 k resistors in series (I haven't dissected this part to close yet). This mod all leads to the mic connection.

I am guessing that this might have been used to connect a sound card for the digital modes. has anybody seen this mod before?

Also, my phone company is Comcast, so my phone is via internet is that a problem using an old fashion phone patch?

Thanks Guys

Greetings to All,

Back in October 2012 I began a thread with message #39480. I received many good tips from a number of members but I had to set aside the repair of my TS-830S. The week I planned to put off the project lasted a little longer. K9TW, Terry gave me a good lead and over this past weekend I got back to the project and found L40 on the RF board is open. I also followed Terry's advise and got a new RL1. I also just ordered a new set of sprockets so this will be more than just a small overhaul. I will get back with the group just as soon as I receive all the parts.

Thanks again for all the great advice. I am learning a lot about this radio.

Andrew,

Welcome, and nice to hear that your 520S is working great. There are numerous places to obtaina "spare set of tubes." RF Parts, Antique Electronic Supply...and of course EBAY, just to name a few. Bewary however...when a seller states: "Tested fine in my "golly-gee-whiz" model tester." Testers will indicate shorts...etc...but will not tell you that the tube(s) in question will
function in the real RF environment. See if they have a return policy for non-functional tubes.
The best way is to test the 12BY7A & the 6146/A/B/W final amplifier tubes in actual operation.
Keep at least one spare of a KNOWN GOOD driver, and(preferably) two final amplifier tubes(one set) You do not need a "matched pair."

The 520(S) series is getting rather old...as we all are...hihi.....two of the most common problemsare broken tuning cores...and dirty/corroded parts...have you inspected the tuning cores under bright light and magnification yet?
If not do so...and before you decide to align the rig...come back and get some pointers about
those tuning cores..BEFORE you break them!

Hello Terry, I found out why the radio went dead. It was a fuse on my power strip. I found that working on radio's is not a good thing when you're tired. I won't make that mistake twice.

Now onto the rf drive test you asked me to perform. I checked each band with the SG switch in the OFF position, mode set to CW, heater ON, VFO set to 200, and the meter set to ALC. A dummy load hooked up to the output side of a wattmeter was used for all the tests.

First I peaked the radio with my wattmeter. I could actually read a small amount of power, or at least see the needle move. I then peaked the drive control with the meter set in the ALC position. I adjusted the Carrier Level Pot until I got a full scale reading and marked down those readings in my notebook.

The readings are as follows:

160 - 2
80 - 3
40 - 4
20 - 4
15 - 5
28.200 - 9 **
28.700 - 9 **

I wasn't sure what you wanted me to do with 10 meters so I gave you readings with the bandswitch in the lower and higher part of the 10 meter band. In both cases I left the VFO at 200.

Next I powered the rig down and bled down the caps with my chcken stick (twice). I tried to see if anything looked burned or out of place. I also unplugged the radio. I like living! I couldn't see anything that looked burned or discolored.

I'm guessing the next steps are going to be testing of the final section? If so, I will be "VERY" careful.

I'm going to get out my Amateur Radio Handbook and try to study up a little on tubes. I have not (at this) point changed the finals, but the ones that are currently in the radio were taken from a radio that was working. If fact they are almost brand new. I also checked them on my tube tester. I know that doesn't necessarily mean anything, but it's another test and I figured it couldn't hurt. The tube tester is an old Hickok. I noticed that the ALC values seemed to climb as I went higher in frequency. I'm guessing that the 10 meter band shouldn't be that high? I'll wait to hear what you have to say about that.

Leonard/WV3P

Hello group,

Thanks for a high-res schematic mailed to me off-list (thank you Mike W5RKL!) I have followed the high-voltage from the main transformer to the HV unit X43-1110, where something is happening. There are three 680kOhm resistors in series (R2, R3 and R4) which I am unable to meassure (probably due to the high-voltage stored in the capacitors), but at the HV terminal I meassure only 45V when the radio is powered up, which I presume is incorrect. There is aproximately 890V on the 800 terminal going in to the board. Is it possible that one or more of the 680kOhm resistors have let out the magic smoke? There is no apparent optical sign on any of them. They seem to be too big for 1/2W resistors so I guess they are 1W resistors?

Which capacitor should I short to eliminate any high voltage and ease meassurements? Is it enough with the two high voltage capacitors? I was thinking of using a resistor of some size (10kOhm?) not to harm the capacitors. Is that a good thought or am I coward?? :-)

Thanks for any advice!

Marcus,

What steps did you take that tells you the 3 680K 1/2 watt and the 1
100K 1/2 watt series resistors on the HV Unit board have smoked?

Leonard:

If I understand your chart it appears you are saying that you got full scale ALC deflection on each noted band with the Car Level Pot at the positions you have logged on your chart. It is typical to have to use a lot of Car Level on 10 meters. Your position numbers on the other bands look good.

If that is so it is telling you that you have three necessary parameters for good RF drive:

1. You have cathode emission from the 6146 final tubes
2. You have proper operating dc bias voltage on the control grids when you flip to Send
3. You have proper RF drive level from the plate circuit of the 12BY7A tube to the 6146 control grids to overcome the bias offset and cause grid current to flow and to bias on the ALC amplifier transistor to reduce the ALC bus voltage and cause the meter to drive up scale.

This means you do not have an RF drive problem that is causing very low RF output. Problem has to be in Plate circuit of the Final tubes and down stream from there. First need to confirm spec dc voltages at the Finals.

1. No or very low screen grid voltage. I would measure at Pin 3 of the 6146 final tube sockets. (must have SG switch on).
2. No Anode voltage. Just because you read approx 900vdc on your panel meter in HV position does not mean you have 900vdc at the 6146 tube plate caps (top of RF plate choke in PA cage).

Also, are you absolutely certain that your external wattmeter is good?

Can you measure the RF output voltage across the your dummy load resistor?

If you had no external wattmeter you would load your rig by alternately adjusting the Plate Tune and Plate Load capacitors for maximum Relative Power by using the RF detector position of your panel meter without exceeding approx 200 ma Ip. That meter indication proves you have RF voltage at Pi-network output (across the Plate Loading capacitor) but does not prove you have voltage across the dummy load.

To prove you have RF output power need to measure the RF voltage across your 50 ohm dummy load. You can do that with your O-scope. At 100 watts output power you should see approx 71rms volts drop across the dummy load resistor or approx 200v P-P on the scope.

If not easy to measure across the dummy load resistor can measure inside the PA cage at the bare tinned bus wire soldered to center pin of the SO-239 connector. Must be careful doing this as in close proximity to 900 vdc.

Need to use a 10X probe and make sure not exceeding max AC rating of the scope probe. Most standard 10X probes are rated at max of 300 vac.

If you have no RF voltage across the dummy load resistor you may have a bad contact on your Ant TR Relay. Would pull it and clean the contacts with copy paper wetted with Deoxit.

Summary:

Verify you have spec Anode and Screen Grid voltage for the 6146 Finals. If you do then measure RF voltage across the dummy load resistor. At 100 watts output should be approx 200v P-P. If no RF voltage or very low RF voltage across the dummy load resistor then pull the Ant TR relay and clean the contacts. Can also swap the two relays.

Mike,

On the HV unit I meassured the voltage at the 800 terminal to about 890V DC and the voltage at the HV terminal to about 45V DC, and didn't check the schematic enough. When I double check now I realise that part of the HV unit is a voltage divider only to meassure the high voltage, not to distribute it or anything else. My error (I blame it on the late hour last night... ;-), thanks for the heads up! I simply have to continue my search.

This is a great Ohms law example for series parallel resistors.

In RX mode the divider is approx 2 meg ohm divided by 100k ohm or a 20 to 1 ratio. With 900vdc applied across it then 900vdc /20 = 45 vdc. That is why you are reading approx 45 volts. The first time I saw this I about had a heart attack. How can they apply 45vdc to the 500ua meter movement! I came very close to changing out all the divider resistors thinking there was a failure!

Your panel meter is a 500 ua movement with internal R of 800 ohms and FSD of approx 0.40 vdc.

When you flip to Send with the meter selector switch in the HV position the RL-1 aux relay applies your meter movement directly across the 100k divider resistor. Now you have 100k resistor in parallel with 800 ohms. So your divider ratio has now been changed to approx 2meg ohms divided by 800 ohms or approx 2500 to 1. So that 900vdc applied across the divdider is now 900/2500 = 0.36vdc. That is a level that the meter will like and deflect close to the 900 vdc graduation.

You can prove this by monitoring the HV voltage and watch the 45 vdc drop to approx 0.35vdc when you flip to Send with the meter in the HV position.

A real KW Hybrid practical example of Mikes Basic DC Theory videos.

Of course the voltages you will measure will vary based on the tolerance of the four divider resistors and how they have aged over the years. You can replace them all with precision resistors, but kind of silly as the panel meter is calibrated in 50 vdc divisions and about best resolution is 25 vdc. I service a few where I find 1% resistors have been installed. Doesnt hurt but not necessary.

Meter never intended to be a precision voltmeter.

I am sorry the values I cited are for the TS530/830 panel meter. Will be very similar and same principle for the TS-820. Panel meter is slightly different int R, but you get the idea.

Of course as you noted the HV terminal and its associated divider string has nothing to do with no Anode voltage at the plate caps of your 6146 final tubes. A very easy thing to trouble shoot. Just have to be careful measuring the voltage.

Terry, I measured 1000 VDC at the top of the RF Plate Choke with the SG switch ON.

I measured 271 VDC on pin 3 of the 6146 finals.

I haven't gone any farther with testing today. I'm letting it sit till tomorrow.

To asked if I knew the watt meter was good. Evidently the answer is a big "NO"!!

Here are the RF readings P-P as measure on my scope.

160 - 200V
80 - 200V
40 - 200V
20 - 200V
15 - 180V
10 - 190V

Looks like there's nothing wrong with the rig?? If so, I think I may have a bad wattmeter. Wouldn't that be great?

I won't celebrate until I hear from you first, (Fingers & Toes crossed)

Leonard

Appears you took the 6146 anode and screen grid voltages in RX mode only. That is OK but need to take then in TX as well.

It appears you are saying that the P-P rf voltage readings taken with O-scope are across the dummy load resistor?

If that is true, then you have RF output of approx 100 watts being dissipated across that 50 ohm resistor and you have an issue with your in line wattmeter.

I would load up into your antenna using the RF relative power position of your panel meter (dont exceed approx 200ma) and try to check in to a local net and get a signal report. ECARS @ 7255 might be a good one to try.

I have loading instructions on my website K9TW.com, but if you literally follow the instructions in your Operating Manual you will be fine.

Yes, I came to the same conclusion Terry. Seems I'll have to learn how to trouble shoot a watt meter. I took the rf readings as you suggested by attaching my probe to the center pin (inside the chassis) on the so-239 jack. I was "VERY" careful doing that since anything inside that RF section scares the heck out of me. I did get nailed about 10 years ago when I accidentally brushed my arm over the tops of the tubes in the final of an old Swan 250C. I never want to do that again!!! It blew me right off the bench, and luckily I'm here to tell the story.

I will take readings tomorrow off pin (3) of the finals in both tx & rx, and report back to you. I feel that I'm very close to buttoning this thing up after approximately 3 months work.

Leonard:

OK to measure the rf voltage at the SO-239 conn inside the PA cage, but realize that does not mean you have any RF at your wattmeter or dummy load or antenna.

If you have an open coax jumper or open anywhere in the antenna system downstream of the SO-239 you will still read high RF voltage at the output of the rig and will still see RF relative power on the panel meter and will see IP readings and the rig acting like it is loading. It will load differently with the dip not occuring at the white band specific locations, but it will make you think you are loading. The risk with loading in to a very high impedance (very high VSWR) is that the RF voltage will be high and could arc over the Plate load capacitor plates.

With nothing connected to the SO-239 the load presented to the final tubes is essentially the resistive load that the RF detector diode resistor divider network of approx 11k ohms presents.

So ultimate proof of RF output power is reading RF voltage across the dummy load resistor or in old days would use a Thermocouple RF ammeter and mount it in nice box with SO-239 on each end and place in series in the feedline. Then would load for max RF current. At 100 watts output that would be approx 1.4 rf amps. (1.4 x 1.4 x 50 = 100 watts). Only issue was the meter response was a little slow as the RF current has to heat a thermocouple which in turn produces a mv output voltage and dc current to drive the meter movement. This was all before watt meters became common place.

I didn't have a chance to measure the output across the dummy load yet, but I did have some time to take the measurements on pin #3 of the 6146 tubes on transmit & recieve. I checked both tubes during the tests. They were both the same, so I'll only give you one set of voltages for both the tx & rx on each band.

The tests were done running into a 50 ohm dummy load, and each band was peaked on tune first, and then cw using the wattmeter as a general indicator since it seems fine for that.

The first reading will be recieve, followed by the transmit voltage. VFO set for 200 on the dial for all tests.

160 583/489
80 582/428
40 575/490
20 582/492
15 583/491
10 583/550 *** I only tested the first portion of 10 meters. (28.000 - 28.600)

I just found that the little plastic pointer on the plate is cracked and doesn't really read properly. I'll have to try to find one somewhere. It's spinning on the shaft.

Hope you're enjoying Dayton!!!!!

OK, so I have the dummy load and checked out what you asked about.
Plate current during transmit is fairly steady at 60. Of course it takes a minute or so to warm up.
HV drop is not even 10% I don't think. Very small drop.
I did have to drop the RF Volt down some in the Plate and Load Tuning. The amount was reading at full scale and instructions say that it should be at 2/3 scale.
Anything else to check?

Terry K9TW,

Thanks to you, Terry, K9TW, for the concise advice.

A wealth of information,

Good to have a group like this , where the techies hang out,
with helpful experiences and advice.

Finally got around to pulling out the VFO box.
The main shaft was binding on the #2 drive gear.
Looking from the Knob side,
this gear set is on the back wall of the gear box.
The base of the main shaft has a bushing on that back wall,
and a drive gear engaging #2.

It appears that the problem was that earlier in this 830's history
someone had put lube on the gears, and it had picked up dust etc.
and became lodged in the teeth .
These gears are designed to maintain a tight mesh.

Using a tiny screwdriver, I was able to gently scrape the grease & dirt off,
I administered partial drops of very thin 'electronic' oil, with a toothpick.
I spun the knob gently, for several minutes,
only as far and as easy as the shaft/gears allowed.

Seems to be freed up now.
In the next few days, I'll put it back on line,
and crank it up for working CW.

Surely, somebody is wondering why "CW" with a Cadillac rig ?
Well, my first station was K4KKQ, 1958, and we all did not do SSB back then.
At the Naval Air Station Norfolk, VA ,
we had several CW ops from WWII who could work CW at 65 wpm !
SSB was the new mode at that time.
I do have two mikes for this Kenwood, stored nicely in the attic.
I still enjoy doing things like when I was young
... still using my 1940 Bug.

BTW, just worked, confirm, Germany, on 1 Watt, LongWire, 20M.

Thanks to Terry, K9TW, for the concise advice.

Glen Ellis, KK4LPG.

Leonard

Suggest you re-measure the 500vdc plus on the screen grids of your finals?

What did you use to measure this voltage?

Should be approx 260vdc.

Terry K9TW

COLD, WET, WINDY!

Other than that is was fun!

Yes I dont know how you can have 500vdc screen grid voltage?

Only place in radio that approaches that is the center of the two series HV filter caps.

From: chastizer4@...
Topic: 48796 Message: 48796

I am trying to help a fellow out with his TS-520 which is having very low output issues on all bands.

I get 60mA of idling current with meter on IP, HV shows 900 V, ALC deflects nothing at all. I've tried both CW and SSB. Drive and Carrier make no change. I swapped the drive tube out with what is supposed to be a new one with no change. Based on suggestions I tried listening on a second radio at a given frequency and into a dummy load the 520 is transmitting a nice tone while trying to tune. Inline power meter shows maybe 1 watt out. I could sure use some suggestions on where to look next. FD is soon upon us and I know he's itching to get on the air.

Thanks!
Charlie - AC6ZX

Larry,

OK, you need to do a couple of more things..OK?

With rig warmed up, SG switch on, Power & Heater switches ON

MODE SWITCH to "TUNE"
Meter switch to "ALC"
"CAR" control turned up to around the 9-11 o'clock posit
SEND switch to "SEND"...and adjust the "DRIVE CONTROL"
for max reading...if too high...back off on the "CAR" ...watch needle...does it fall back towards zero or remain steady? If it falls off...usually indicates bad 12BY7A driver tube.

Finish tuning up for max power output...keeping in mind not to let the Ip get to high
say 225mA or so

With MODE SWITCH in "CW," and meter switch still in "RF" position. put send switch to send...note the relative power indication...keep rig keyed for about 5-8 seconds and see if the RF reading falls off....if so...usually bad final amplifier tube(s)

Your HV(high voltage) should be around 750VDC or more, with key down in CW.

Have you been able to recreate the slow power drop-off? It would be interesting to see what you show for HV, Ip....when this happens. I also suspect that you may have failing HV capacitors too.

Have you tried taking voltage measurements at the driver and final tubes. Use the 520 schematic and service manual as a guide. The manual has voltage charts to compare you actual voltage measurements with.

When measuring the HV at the Rectifier Unit, measure the actual HV to the final tubes on the "800" terminal. The HV UNIT board has 2 terminals, one labeled "HV" which is the HV meter switch connection and the 800 terminal which is the actual final tube HV that's fed to the Final Unit and the plates of the 6146s. You can measure the HV at the 6146 plate caps as well which should be the same as it is on the Rectifier Unit's 800 terminal.

The HV applied to the 6146 plates is present all the time as long as the main power switch is turned ON and the 520 is plugged into a 120VAC outlet so be careful!!! Use caution when measuring any voltages especially the HV.

Charlie,

Has this rig been owned by the current owner for awhile..or a "new" acquisition?

You make no mention if it receives...but check the small round 9 pin socket on the rear to see if it has the "shorting plug," or a jumper wire between pins 8 and 9.

SG SWITCH ON??
can you see a glow from the driver and final tubes when the "heater" switch is turned on??
are the finals good?? a tubes tester will not tell you if they will work properly in the RF transmit environment.
The no ALC in tune is a common problem. Mostly it's resistors 5 & 6 (56k each) on the rectifier board.

You'll need to do a voltage check

Hello,

Name is Brian. I've been a proud owner of a TS-530SP since '91 and have been reading all the posts here on a daily basis for the last three years or so.

That being said, does anyone know where I can get my hands on a replacement for the pointer portion of the PLATE control? No big deal; have lived without it for a few years now, but thought I might as well finally ask the group if they know of one that might be available.

Thanks!
Brian KB5PLA

Brian,

Once you get a new pointer, make sure you put some form of lubricant on the shaft, this way if you have to remove it, it wont break.

Thanks Joe, This rig is new to the owner. It's rather dingy compared to most pics I've seen posted. Receive seems to work well with decent S-meter movement, SG switch on, 56K resistors showed 122 and 262 volts so I think they're ok. All 3 tubes have a nice orange glow in the dark. And jumper on rear is in place and making good contact. Charlie - AC6ZX

Charlie,

  Your voltage measurements are within nominal specs...except for your notation regarding PIN 2. The voltage here is AC volts. It is the "heater" circuit...it should be about 12.5VAC or so on Pin 2 of the front 6146 and about 6.5VAC or so on Pin 2 of the rear 6146

Joe,
Thanks for the input.
With the drive control adjustment, the reading holds steady, no fading. If the Drive Control is adjusted just a few degrees either way, it drops to zero. But holds steady at max power.
The HV reading is steady at 800V.

Keep in mind that it dropped out over several days and has remained that way. So I cannot recreate it. It never recovered.

48809. Re: [TS-520_820_530_830] 520S - transmission faded out to nothing

Hi Group I'm finishing restoring my TS820S. When it came to TX tune-up I'm having problem(s) with the Plate adjustment. The plate dip settings are all over the place and not even tracking close to the Plate markings i.e.
7.0 MHz band Plate dip to the far left nearly off scale.. Every Band is far off the Plate Markings.....all else is normal. Ip is 60 mA, Drive and Loading are fine also. Tuned Ip is 225mA, HV is 750VDC.

Am I missing something? Is their a tuning adjustment to make the plate dip track the panel band ranges??

Interesting note. I opened the final cage to look for problems top & bottom a fould tatty looking 6146's. Some
ding-dong installed two plain 6146's with a date code of 1959, 1961....why??? I in stalled two 6146W's instead.

Also the plate variable cap is meshed at the 12 o'clock position when the plate knob if at 9 o'clock setting.

My 820's is really clean and works great on receive.....next the TX.

My plate tuning knob goes from CCW end 8 O'clock to max CW to about 5 O'clock. The plates are fully meshed at the far CCW position and un-meshed at the max CW position, and that corresponds somewhat with lowest to highest bands.
Your tuning knob may be loose , slipping on the shaft and needs repositioning and tightening of the set screws. My plate dip was not always EXACTLY on the marking on the face of the rig !
I hope you start tuning at the minimum loading setting (fully meshed loading cap).
Good luck, I have had my TS520 for over 40 years I believe, since new, and it was just retired this year.

Bill,

Sounds like the shaft from the front panel to the plate air variable has slipped.

With the plates of the plate air variable FULLY MESHED...your pointer should point to around the 9 o'clock position....50 % meshed(kinda looks like a "pacman") pointer to about 12 o'clock...and fully unmeshed...the pointer is about 3 o'clock. I take it..and hope.. that you have beenusing a dummy load for your tests.

Also, don't forget to neutralize those finals. The 6146W's are fine..I don't need to open a can of worms..discussing the pros/cons of the various models of the 6146 series of tubes. That's
been covered already. There's a good article in the "FILES" section regarding this topic.

48813. TS-520S low power output

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-05-21 01:38:20 UTC
From: jbdkz@...
Topic: 48813 Message: 48813

I have went through section Calibration, sections 4.4 through 4.13, in the TS-520SE Instruction Manual. All readings appear normal as in the book. If I set the mode to CW and transmit for 3 seconds into the dummy load built into my MFJ-949C it reads only 5 watts. I also notice very low power on the MFJ meter during normal SSB operation.

Can you give me some tips on how to troubleshoot this issue?

Thanks,

John

John,

When you say

"very low power on the MFJ meter during normal SSB operation"

are you saying the MFJ-949C's watt meter is showing between 20 and 30 watts on voice peaks when transmitting on sideband (USB or LSB)?

Set the TS-520SE meter switch to IP. What is the meter indicating with the 5 watts you say is shown on your MFJ-949C watt meter in CW mode?

If you adjust the CAR control clockwise in CW mode does the 5 watts indicated on the MFJ-949C watt meter "increase"?

Are you using the MFJ-949C internal 50 ohm dummy load?

The MFJ-949C internal 50 ohm dummy load has a maximum constant carrier time of 2 minutes (stated in the 949C manual under the paragraph titled "ANTENNA SELECTOR").

Greetings Again,

I replaced L-40 on the RF board and have an RF signal on test points TP-3 and TP-4. There is no RF on TP-2.

On Q-3 and Q-4 I have DC voltages. I also have RF on the gates but no RF output.

Is there a source for the SK125's? Is there a substitution?

Thanks in advance for any help!

Ron - KI4TI

Thanks for clarifying, Joe. I rechecked pin 2 and got the expected AC voltages. The 12BY7A had the following: 1: 0.3/4, 2: -38/1.4, 5: 13AC, 7: 346/314, 8: 263/232, rest: 0. Learning as I go here. It looks like Q10 (RF board) is a player here so I wanted to check it also. For safety sake I opted to check test points. DX: -95/-56, ALC: 3.1/3.1, FG: -95/-56. Seems ok? Do these tests tell us about tube conditions? It often seems in reading the early posts that tubes are swapped when all else appears to be ok. I'd love to get this baby going so I can go find one for myself. These hybrids are really cool! Thank you, Charlie - AC6ZX

Ron:

I think you are a little confused about how the receiver works.

Do you mean L41 Ant step up transformer? If so, how do you know you installed a good one? Did you bench test it before installing it? If not, you will have to test it in circuit. Easy to inject at TP-1 and measure at the wiper of S1-2.

TP-3 is not off air signal path. TP-3 is your VCO signal which is the LO (local oscillator) signal for your TX and RX Mixers. Should be approx 1.0rms rf volts and at the proper band specific frequency noted in the service manual for PLL alignment.

TP-2 is your 8.830mhz RIF output and will be a very low level signal. If you are trying to measure off air signal level it will probably be on order of 5uv or less. How are you trying to measure it? It is very rare for Q3/Q4 to be bad.

I assume you have no receive? Is that correct? If so, how are you troubleshooting?

Are you using the Marker signal as your RF Sig Gen or using a RF Sig Gen and injecting and measuring along the signal path?

If you have no receive and nothing out the speaker can do a split approach to pretty quickly find where fault is at. Have you determined that the IF and Audio chains are working? If so can then focus on the path from the SO-239 to the RF board and on the RF board.

Can inject 8.830mhz at TP-2 and see if rig comes alive. Inject -53dBm (500uv) and should see approx S9 on S-meter and good loud tone in the speaker. If not, then move RF Sig Gen to the IF board and inject at Conn 6. You do this because common to have bad molex connectors in the path.

If rig comes alive when you inject 8.830mhz at TP-2 then you know the problem is on the RF board or in the path from the SO-239 to the RF board. Have to inject at SO-239 and work way toward the RF board or work from the RF board back to the SO-239. So if you inject at the SO-239 and measure RF at TP-1 then you know Ant TR relay contacts, Xvter DIN switch, RF attenuator switch, and Molex Conn 3 is good.

If you lost L41 due to ESD or accidental TX RF you may have also lost Q1 RF amp.

Thank you Mike for your reply. My answers are in red below:

John,

When you say

"very low power on the MFJ meter during normal SSB operation"

are you saying the MFJ-949C's watt meter is showing between 20 and 30 watts on voice peaks when transmitting on sideband (USB or LSB)?

Answer: On the MFJ-949C, I have the button set to 30Watts and Dummy Load. Mode on my TS-520S is set to CW. If I flip to transmit the Forward Wattage on the MFJ reads "50" which I believe translates to 5 Watts on the 0 to 300Watt scale.

Set the TS-520SE meter switch to IP. What is the meter indicating with the 5 watts you say is shown on your MFJ-949C watt meter in CW mode?

Answer: Will try this tonight.

If you adjust the CAR control clockwise in CW mode does the 5 watts indicated on the MFJ-949C watt meter "increase"?

Answer: Will try this tonight.

Are you using the MFJ-949C internal 50 ohm dummy load?

Answer: Yes

The MFJ-949C internal 50 ohm dummy load has a maximum constant carrier time of 2 minutes (stated in the 949C manual under the paragraph titled "ANTENNA SELECTOR").

Answer: Yes I am aware and have only did a few 2 second CW bursts into the Dummy Load.

John,

You need to make sure you sign your messages with an approved message signature! If you are a licensed ham then an acceptable message signature is your "name" followed by your "call sign". If you do not want to include your call sign then your first name. If you are not a ham then your first name.

Every member, regardless whether they have been a member for years, a group Moderator, group co-owner, or a new member, must add an approved message signature at the end of each message they post! This requirement was stated in the auto messages sent to you when your application for membership to the group was approved.

Hi all.
Last night I purchased my first HF rig. I got myself a Trio T-530s with matching Kenwood ATU.(AT-230)
It did come with owners and service manual as well.
The radio came with no microphone, which is a round 4 pin type, so I will be on the hunt for one of them
Also the radio has a mod done for what appears to be for 28Mhz.

So, on the to-do list is

Read and understand the manual (and find the min power settings) as a foundation licence holder I am limited to the power outputs
Get used to the dials and setup options for the radio
Obtain a suitable antenna, might just be a long wire for now for RX only, but will see what happens.

Overall I am please with the radio and price I paid for it.

The hard part now is finding a location for it on my desk!

So for now, 73s

Terry,

Thanks for the information you supplied. I have yet to go beyond the RF board. I've had a bit of confusion here but also a lot off Ah-haa moments.

Originally the problem was no VCO signal at TP-3 but the signal was on the coax cable from the PLL unit. I tested the pi-filter on the VCO input on the RF board and found that L-40 was open.

Now that I have VCO distributed on the board I followed the signal through the TX mixer and have a signal TP-4.

Regarding the RX mixer I have DC voltages at Q-3 & 4 and VCO signal on the gates but no signal input into T-2 or on TP-2. Would I not have a signal on the drains of Q-3 & 4 just as I have on the TX mixer semiconductors?

I will need to take some time to study the IF and AF boards.

Thanks again,

Ron - KI4TI

Ron

OK very unusual to find L40 open. I thought you were confused about L41 a much more common RF board failure. A good find on your part.

TP-4 is the TX Mixer (Q6/Q7) output to the control grid of the 12BY7A Driver tube. You should have approx 2.0 to 3.0 rms RF volts at TP-4 in TX mode. TP-4 is normally measured after loading to 100 watts out and then flip Screen Grid switch off to take the TX Level Diagram readings.

Because you read 2 rf volts in TX mode at the output of the TX Mixer does not mean you should expect to read 2 volts at the output of the RIF mixer or anything close to that level. You are comparing apples and oranges. TX RF drive levels and RX RF signal levels are very different animals. The 8.830 mhz RIF signal will be in the uv (microvolt range). What you read at TP-4 in TX mode has nothing to do with receive and can make no comparison between the two mixers other than approx same level of VCO LO signal level for proper mixing action.

Only other thing in common with TP-4 is the Mixer tuned circuits are shared between TX and RX modes.

It sounds like you are saying that you have proper DGS dc voltages at Q3/Q4 FETs in Rx and Tx modes. If so that is good and it means they are being biased on and not likely they are bad. If shorted would likely see Drain voltage on the Source leads.

I will say again that the 8.830mhz rf signal levels at TP-2 are very low and average ham cannot measure it. Again how are you trying to measure the 8.830mhz RIF level at TP-2 and what would you expect it to be? If you are trying to use a RF probe and DMM or VTVM you wont read any rf signal level. Way below the barrier voltage of typical germanium signal diode.

You need an O-scope or RF millivolt meter to measure any rf signal level at TP-2. With rig on dummy load should read approx 5.8mv rms and with Marker turned on approx 6.0mv rms. Almost all of that level is VCO LO leakage and not the 8.830mhz RIF signal. Been awhile since I measured it (have to use the Low pass filter option on your scope if it has one) and the actual RIF is in the 300uv rms range.

Lacking above test gear one other thing you can do. If you have background noise in the speaker then you can take a metal tool and tap it on TP-2 and noise should drop away and S-meter should go up scale. Dont leave tool or your finger on TP-2 very long just tap it on and off. If noise drops and S-meter goes up scale it means your IF and AF chains are working and you can concentrate on the front end.

I had a lull on the bench as I had to order a part to restore transmit function to a rig so thought I would stop in and see if could quickly help someone.

I am sure others here can help you. Just go at it in systematic way. Since you found bad L40 it appears you have some knowledge, experience,and test gear so I am going back to the bench.

I just picked up a new Hakko 808 de-soldering gun, on the recommendation from Dick Housden W0NTA. I have to tell you, this gun is awesome. The parts just fall off the board using the new gun.
They might be hard to find these 808s because Hakko has a new model out to replace it. But, I found that MCM Electronics has them and on sale for $199. The purchase includes spare parts and a case to store everything. It's a very good deal. Also to mention, MCM is carrying Vishay ceramic caps at prices lower than Mouser. It's a good selection too, from about 250v to about 6kv voltage range.
I just wanted to give you guys a heads-up on the Hakko, if you're thinking about buy one.

Dont know how I ever functioned with solder wick!

Hakko is really a must when removing ICs. Makes childs play of it. Also, less likely to lift a pad in the Hybrids, but still can if not adjusted properly. Must make sure tip is touching the component lead as well as the pad.

Wish we had more time to chat at Dayton. Left early on Saturday as could not move inside and tired of the cold and wet. Too soon to think about next year but right now not likely to attend.

A long way to drive and a lot of expense money to buy the Rigol. Bought a Mini-circuits combiner and a Heath IM-18 VTVM for $5.00 on a whim. Of course what price can I put on seeing you, Dick, and Mark and getting to eat at 45 year old Marions!

Thank you for the tip on proper signature, I joined over a year ago an don't often post.

With regard to the following questions:

Set the TS-520SE meter switch to IP. What is the meter indicating with the 5 watts you say is shown on your MFJ-949C watt meter in CW mode?

Answer: IP (Plate Current) is around 100ma

If you adjust the CAR control clockwise in CW mode does the 5 watts indicated on the MFJ-949C watt meter "increase"?

Answer: Yes! once turned clockwise in CW mode the watt meter on the MFJ increased to about 75 Watts. I imagine this is RMS power. What should the output wattage be for a correctly working TS-520SE in CW mode?

Thanks,

John

John,

I could be wrong but from your responses, it appears your TS-520S alignment of the RF Unit coil pack may need to be check and if necessary, a slight adjustment.

You can calculate the approximately DC input power and output power by performing the following simple math calculations.

Note the HV and IP indications with full output. Multiply the HV indicated on the meter by the IP indicated on the meter, this will give you the approximate "DC" input power in CW mode. For example, if the HV is 810VDC and the IP is 200ma then the approximate DC input power in CW mode is 162 watts (810 x .2 = 162). The typical efficiency of the Class AB1 final amplifier in the KW hybrids is between 55% and 60%. Therefore, assuming an efficiency percentage of 60%, the approximate power output in CW mode would be 97 watts which is normal for the 520SE. Naturally 55% will result in a lower power output, approximately 89 watts at 55%.

Terry,

I appreciate the time you are taking to explain the RF board to me. I did the "tap test" and I have no signal. I also do not have any background noise in the speaker. Definitely more problems than the L-40.

I do not have much of any test gear but will get some. In the meantime I have buttoned up the rig and will spend the next bit of time thoroughly studying the receiver along with reviewing all the information in the Handbook regarding various circuits.

I am sure I will have many questions and hope that if I cannot find the answers in previous I can post them here.

Thanks again to all,

Ron - KI4TI

Charlie,

I have not been able to find my notes on the 520 series driver voltages, but looking at the schematic of the 820/530/830 series...the voltages you show are within operational norms. Q-10 on the RF board...I believe is the ALC amplifier. If you have a good 520(s) service manual, I think nowwould be a good time to run voltage levels stated on Pg 44 of the service manual. Also, it'seasy to do...remove both relays and clean the relay contacts.

Have a safe Memorial Day weekend

Well it is not easy to troubleshoot loss of Receive without some modest test gear.

You can test the Audio stage by connecting a test jumper to the wiper of the AF gain pot and touching your finger to the other end and should hear a hum in the speaker. Can also inject audio from a tape recorder, lap top PC headphones output, MP-3 player etc. May have to go to Radio Shack and buy a patch cord. Pretty easy to eliminate Audio stage as cause of no receive.

If you prove you have good Audio Chain then not as easy to test the IF chain. Can use a low cost LC type RF signal generator like a Heath IG-102 or Eico 324. Can get these for under $50 off eBay. Can use them to generate a 8.830 mhz RIF signal to test the IF board.

If you have another rig can set them side by side and jumper between them.

If you are getting first set of test gear suggest something similar to following:

1. Heath IM-11 or IM-18 VTVM or similar and RF probe
2. LC oscillator type RF sig gen
3. Cheap Frequency Counter (Can buy a new Victor or Sonometer brand for $100.00)

48841. Newark has deal on HV Caps

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-05-24 03:14:13 UTC
From: Chris Kepus
Topic: 48841 Message: 48841

In case anyone else is planning on changing out their HV caps, Newark has a great promotion going on these and many other of their HV caps.

I ordered some of the following: Note that the diameter is the same as stock which means you can use the existing clamps.

Description: CAPACITOR ALUM ELEC 180UF, 500V, 20%, SNAP-IN; Product Range:NICHICON - GN Series; Capacitance:180ÏF; Capacitance Tolerance:ñ 20%; Voltage Rating:500V; Diameter:35mm; ESR:-; Height:30mm; Lead Spacing:10mm; Capacitor Case Style:Can $3.77 ea.

Also ordered these for my other PSU□s needing new caps.

Description: CAPACITOR ALUM ELEC 120UF, 500V, 20%, SNAP-IN; Product Range:NICHICON - GN Series; Capacitance:120ÏF; Capacitance Tolerance:ñ 20%; Voltage Rating:500V; Diameter:30mm; ESR:-; Height:30mm; Lead Spacing:10mm; Capacitor Case Style:Can $2.65 ea.

Good shopping no connection with Newark. Just passing on some decent pricing news I stumbled across.

73,

Chris

Charlie: There are plenty of scope tutorials on line.
Start with your calibration output on your scope to see if you get a trace: Try .2ms/div and .2V/div using the calibrator output. You should get a calibration trace.
A good starting point for HF on your scope is .02ms/div, this should give you a trace from 3-30 MHz.
Output from driver is several volts, so start with 2 V/div
You can look at the manual and see where you can measure things
like TIF into the RF board, DRV out (driver tube out, plate), OSC.
These are on the 520 RF board, on connector pins.
OSC is probably working so that would be a place to start on RF board
Anyway, start there and use your scope probe.
Don't be afraid of changing settings on the scope.
Remember it takes a division or two of amplitude before the scope can sync and you need to adjust your sync control.

I hope I remember the settings correctly. Don't quote me.

<TS-520_820_530_830@yahoogroups.com> wrote:

John,

I could be wrong but from your responses, it appears your TS-520S
alignment of the RF Unit coil pack may need to be check and if
necessary, a slight adjustment.

You can calculate the approximately DC input power and output
power by performing the following simple math calculations.

Note the HV and IP indications with full output. Multiply the HV
indicated on the meter by the IP indicated on the meter, this will
give you the approximate "DC" input power in CW mode. For example,
if the HV is 810VDC and the IP is 200ma then the approximate DC
input power in CW mode is 162 watts (810 x .2 = 162). The typical
efficiency of the Class AB1 final amplifier in the KW hybrids is
between 55% and 60%. Therefore, assuming an efficiency percentage
of 60%, the approximate power output in CW mode would be 97 watts
which is normal for the 520SE. Naturally 55% will result in a
lower power output, approximately 89 watts at 55%.

Scott,

Welcome aboard.

By "standard operation," I take it that using them together as intended? The transmitter and receiver will function as stand alones, but IF you want to use them as connected TX/RX then you MUST use the cable, this effectively makes them a "Siamese twin."...or you can go through an elaborate manual switching ordeal...when changing from RX to TX. I looked at the connection diagram...and it looks pretty straight forward

From: Wes Will
Topic: 48847 Message: 48853

If the archives are to be trusted, the cable is simply straight-through, pin-to-pin, except that pins two (2) and five (5) are not used, and pins seven (7) and sixteen (16) are connected together.

Since (from the archive messages) the "series 1300 Hirose" connectors (with the round pins instead of the square ones which the series 1600 connectors have) are more or less pure unobtanium these days, with crazy prices (in the near-fifty-dollar range PER CONNECTOR), might I suggest a dodge I've used in more than a few similar situations before?

WING IT. Make a cable with discrete pins, instead of a single connector, on each end.

It's the same thing Motorola used on old MoTrac and other models of their mobile commercial radios to connect the tuning head and speaker box to the monstrosity of a radio bolted to the firewall or some such place in the truck. Stick the little metal pins in the little holes. Not exactly a challenge.

Use single wires with a pin on each end, covered partially with insulation to give a safe place to grip and insert them if you wish to be all fancified, and CAREFULLY just connect one wire at a time from the remote connector on the receiver to the remote connector on the transmitter. Yes, you wind up with a bunch (about thirteen, looks like) of wires.

When you're done plugging and labeling? Anyone else ever used waxed string to make wiring harnesses?

Zip ties are acceptable modern equivalents, wouldn't you say? And you don't need to remember how to make that knot on the ends of the waxed string to secure the thing.

Plug them in carefully,

one at a time,

and as you insert each one,

NUMBER EACH WIRE, AT EACH END (so you can do it again later),

then use zip ties to make it into a cable bundle. You will have skipped that hundred dollar expenditure and gotten the precise same functionality.

If someone here who happens to own one of these over-priced cables would verify what I just got from the message archives about the pins 7 and 16 being connected together, and that 2 and 5 aren't used at all, then you could go ahead with certainty and make your own cut-rate-cost,

first-rate-function, cable.

Same bat-time, same bat-station, just not same insane-expense for some hunks of wire with metal pins on the ends, and some plastic bits to hold it together. My way, you get everything except the plastic bits. And you get to spend a lot less time trying to find one of these cables or even just a pair of the connectors, and keep a lot of wonga in your own pocket instead of someone else's.

So far as I can see, from the vantage point of never having had money that I could just wipe my hind-end with, paying nearly $100 for a cable as simple as this one, well, that seems just about stupid to me. (Or even the $37.50 which was collected, per connector, when the connectors were last known to be available.)

Just find some copper rod, or some other kind of conductive metal pins of the right diameter (tin a nail if that fits the hole correctly) and make your own. There MUST be something in the junk-box or the hardware store that will supply you with the pins you need. And if a bunch of hams can't figure out how to use heat-shrink or similar to make the metal pins safe to insert by hand, well, then I despair of the whole thing.

Anybody who happens to have one of these connectors handy, would you mind taking a caliper or micrometer to one of the pins on the connector, and measuring the diameter of it? Length sticking out of the connector shell would be nice, too, but not really necessary.

A pin-out diagram in the archives as well as that pin gauge would end any problems connecting "Twins" from now on, wouldn't you think?

Maybe I've had to "make do or do without" for too long, but I just cannot see ANY sense in spending that much effort to find, and then that much money to purchase, a simple chunk of wire with some metal bits soldered on the ends.

Wes: I did the same thing on a smaller plug.
Used brass tubing from craft store (or ACE hardware)
Easy to cut to size and easy to solder the wire into the tube.
Tube will also work for either male or female, if you can find the right size, I think these are small, 2mm?
So maybe another pin substitute would be necessary. The ones from computer connector cables?
I don't know if there is a small enough tube for this connector.
Use the brass tubing as pins and wire the units together so that it works, as you stated.
Then make some kind of form and epoxy the whole connector, all the pins together
Use soft epoxy
You can make a form from pieces of plastic, heat bendable, or use scotch tape.
You can epoxy the new connector while it is in place if you use tape as a separator between the radio and the new epoxy plug body.
Then you can connect and disconnect the plug.
looks funky and takes some time, but it works.

The original pin diameter that I measured is 0.059" (1.5mm). If you use the K&S engineering metal's, 1/16 brass tubing (0.0625" dia) (easily purchased at a RC model hobby shop), it will fit into the female jack (I verified it this morning) and make up your plug in that way.
However, I was going to actually replace all the control cable jacks & plugs with 15-pin D-sub connectors, which are gold plated connections and with metallic hoods, which will make a nice & clean installation and reliable with the gold plating. But, I found the original control cable on Ebay, so I jumped on that instead.
Just keep looking around for the cable, and you will find one.

Thanks fellas! Just a quick update here. Deoxit did the trick. After a thorough cleaning of the pots and the VFO I now have a working radio! When I got it back together and powered up I worked a station in Colorado with 59's both directions. Next I worked HK3TK in Columbia, 2743 miles! Again, solid 59's both ways.
Since my first post I have aquired an SWR/power meter and can now report that I am averaging about 100 watts out with 120-125 watt peaks.

A good source for waxed string is dental tape, which is very easy to work with.. All you Heathkit builders will remember the supplied elaborate wiring harnesses. They were assembled with dental tape.

I worked at the Heath Co. St Joseph, MI plant for a couple of years back in the late 1970's. I would often see the harness assemblers with their huge spools of dental tape next to their work stations. It was quite impressive to watch them (mostly women at that time) assemble the harnesses with great speed and accuracy. I certainly would have been lost doing that job.

From: Chris Kepus
Topic: 48859 Message: 48859

Mark and all,

Attached is a worksheet with the caps and resistors I ordered that includes the Newark stock # and the MFR's PN. If the worksheet doesn't come through, email me direct and I'll send it to you.

To keep things simple for anyone just interested in the caps listed in my first message, here they are: Info in this order:

Newark Part No. ; Manufacturer - Part No - Description

27T9821; NICHICON-LGN2H181MELC30-CAPACITOR ALUM ELEC 180UF, 500V, 20%, SNAP-IN

27T9814; NICHICON-LGN2H121MELB30-CAPACITOR ALUM ELEC 120UF, 500V, 20%, SNAP-IN

Good stuff, happy shopping.

73,

Chris

Scott: If you build your own cable putting several 2-3 inch sections of heat shrink tubing around the wires looks good and keeps it together nicely. I used a long heat shrink tube and covered the entire cable from a Hallicrafters receiver to transmitter. Looked better. No offence to the waxed string method.

> Wally KC9INK

I'm not recommending the waxed dental floss method, that's for sure, but it -does- work. Zip ties are quicker for one thing.

Heat-shrink is good stuff for this, but long piece tend to be kind of pricey.

To save some bucks here, you can use the exterior insulation from a chunk of ruined coax, carefully slipped off the braid/outer conductor.

I usually use the pieces that have soaked up water from being un-sealed and used outside without protecting the ends properly. I get that kind of stuff from CB'ers mostly, sometimes other hams. They generally know better, and certainly do after losing one piece to water.

Can't use more than a few meters of that kind of damaged cable, at most, and maybe not even that much. Usually there's some still good from the middle. The ends are always shot, because of the damage to the insulation and corrosion of the copper conductors. (That's what I use for making the odd coax jumper, those short middle bits.)

The stripped copper gets recycled, the outer sheath makes decent cable covering. The braided outer conductor can be used to shield wire runs for RFI/TVI protection. Salvage, re-use, re-purpose, re-cycle.

Yeah, I'm part Scottish. Your point?

I remember getting a 40-meter (130 feet) section of REALLY expensive hard-line from a fellow, and after trimming it a meter or so at a time (a bit snipped from each end and inspected for damage, repeat until you get to where there isn't any corrosion or water running out, or other signs of deterioration), I wound up with a whole 75 cm. of hard line left. (That's about two feet for the metric-impaired.) SUCH a waste. I was very sad, I was hoping to use some for an antenna of my own.

Back to the cable and connector:

For making the individual hand-made pins into a connector, a bit of effort and two pieces of flat lucite, lexan, polystyrene, or whatever you can scavenge out of some piece of junk, and you can make something to hold the pins in line. A bit of heat to get the pins in the plastic,

Two pieces, so to make a sandwich with the pins sticking through, and put them together with some epoxy to keep them in line, and you're in like Flynn.

Putting a sort of plastic loop on the back side is highly recommended, to give yourself a place to pull the new connector back out (instead of using the wires). Take a plastic milk jug, and cut off the screw-thread area at the mouth. Then take a circle of the plastic out, not too wide and trim it so that it fits between the two rows of pins, then put the second half of the plastic sandwich and epoxy on, to hold it between them. The loop should not be too big, but ought to give you a place on the back of this thing to grab and pull.

Some computer disk drive cables had these grips, generally higher-end models. HP was fairly good about putting these grab-handle sorts of cables in their better PCs.

Oh, yes, I am a fan of all this sort of DIY stuff. Time and scraps, I've got. Money, however, I don't.

Yeah, I know. Sucks to be poor, but not all of us are cut out for cut-throat corporate Murrikah and the big money.

I tried it for a while, and yes, the money was NICE. But I found that I do NOT fit in well with the average neck-stomping ladder-climbers, tending to want to take it personally and retaliate. Boy, howdy did I want to.

In spades, doubled. Redoubled. With brass knuckles or something to help make the lesson stick.

Which was not acceptable, and I didn't do it, but getting that strong desire to take a large chunk out of all of those little weasels, then not allowing myself to give in to the urge and do so, caused a lot of stress. So instead I went back to living in little old Nowheresville and being poor. It was better for everyone, all around.

But it isn't always a lot of fun some ways, retirement particularly hurts the old wallet. But I sleep better and it does make one quite inventive.

And this no longer has much to do with Kenwood anything, all after the loop for pulling the plug bit anyway, so I'm stopping it right here.

Good luck making the new cable, you'll be happy you did. It's good for the mind to stretch it and build something, even something this simple. And you'll be a bit richer in the back pocket area, too.

Hmmm... Good to know, thanks,

Nearest one of those is about an hour and 45 minutes from here, I get there about twice, maybe three times a year...

So, next time I'm in Paducah I'll pick some up and put it in the shack for when I need it.

Otherwise, foolish, frugal me, who has days on end when he can't walk more than a few steps (thank you, Uncle Arthur Itis), and has some cable that can be stripped, will save the buck in shrink tubing, and the two, three gallons of gas.

Put two new items on my website today.

1. Under FAQs-- White paper on what is ALC and how should I set it? In response to off Reflector question.

2. Under Photos-- Picture of my new Rigol Spectrum Analyzer measuring the frequency response of a TS830 Murata K5 455khz Ceramic IF filter. I am still learning how to use this new piece of test gear. It will allow me to put the Sweep generator, RF detector, O-scope, and Freq Counter and all the interconnecting cables aside as all these functions are combined in this one small and powerful box!

If interested can view at www.k9tw.com http://www.k9tw.com

Hope all having great holiday. Finally summer has arrived!

Chris:

Thanks. My first attempt at a website. It is work in progress. I am not very computer literate and trying to do it on the cheap by using Google Sites which is free, but not too user friendly from my perspective.

I plan to add some videos perhaps starting with how to load, various ways to neutralize, how to run TX Level Diagrams to troubleshoot low or loss of RF drive etc. Just not enough hours in the day to do all I would like to do.

As to the frequency response of the Murata filters in comparison to the specs I have to say that this picture was made about 1/2 hour after taking the Rigol out of the box and I did not really know how to use it. Also, didnt have any 2k ohm resistors to terminate the filter with so just used a couple of 1k resistors which I am sure effects the pass band ripple. The Rigol allows you to store traces in internal memory or on a flash drive. I have started doing that for BPF in the TS520 and TS830 rigs.

Still learning how to set it up and use it properly. I have a spare K5 and K12 and plan to compare them to the specs. The K5 is as follows:

Center Freq = 455khz +/- 0.2khz
-6dB = 2.7khz or more
-60dB = 4.5khz or more
Input/Output characteristic impedance = 2k ohms

About only thing we can tell by looking at this first effort is the filter isnt grossly off the specs.

When I get time I will sweep all the filters and post pictures.

I wish I could find KW factory response curves so I could know for certain how much ripple is normal.

If you go to INRAD site you can see some response curves for the filters they sell for legacy radios of different mfgs. Would be nice to have those for the KW factory filters.

Anyway short answer is I know my spare K5 is not grossly off or bad, but cant tell you if it matches the published specs at this time.

Fortunately in my experience seldom have bad xtal IF filters. It does happen but not common. I think I have had 2 bad optional CW filters over the years. I dont know if it is from crystal aging???

Hi Terry-

How were you able to transform the output impedance of the filter (2K) to the input impedance of your spectrum analyzer (50 ohm)?

48871. Antenna for Ts-530s

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-05-28 18:43:27 UTC
From: john
Topic: 48871 Message: 48871

Having just acquired the radio with matching ATU, an antenna is my next purchase. Currently due to licensing restrictions I can't TX so will just be listening for the time being.

Measuring up, I have 50ft in the back garden available to me for an antenna.

My choices so far are

G5RV(or similar), centre fed
Long wire, end fed
or
Vertical HF.

The G5RV might prove troublesome due to being centre fed as it the feed would be right in the middle of the garden and will get in the way
Long wire, would be the next choice with a 9:1 UnUn then fed in the AT-230 ATU

Or vertical HF.

As the ATU has 3 antenna inputs, 2 x SO239 sockets and 1 x wingnut type connector with what looks like a ceramic mount, I could run more than one?

As, I am only listening, could I just use a length of wire with a suitable connector at one end or use the wingnut type connector?

cheers

john

Hi
Thanks for the info and reply regarding the mics etc. Looking in the manual the PO has written a diagram for the mic, as I think the socket may have been replaced at some point. Its now a 4 pin socket, with 4 circular pins (like my Rotel 240 CB radios has)

At the mo, I happy to leave the extra band/function in place.

Stand by for questions regarding antennas. I have seen G5RVs for sale here in the UK.

cheers

John

Subject: Re: New T-530s owner

John:
Good luck with your new radio.
It takes a high impedance microphone. Cheap old CB mikes work, Astatic D104s work, they are crystal, high impedance. Lots of mikes will work. Mike wiring diagrams are in the user manual.
I used a cheap Karioke Mike (600 ohms) once with good results, Xtal mikes are much higher impedance.

Your unit probably has a CB mod to 27 MHZ. 11 Meters.
If you want to restore to the original xtal sometimes you can find an entire oscillator board at a radio shop cheaply.
When I want to restore Xtals, I use Quartzlab, a UK company about $15 US an xtal. You might be able to sell the present Xtal to a CB shop and break even. Sometimes they may have your xtal that they removed.
But if you don't want to use 10 meters,ignore it.

Any antenna will work, a G5RV is nice because you can explore lots of bands, and since it is British, it might work best in the UK. Ha!.
Don't worry about any SWR, the Plate and Load will take care of it. I bought an antenna tuner and believe it is quite superfluous. It is better to have a good SWR but a bad one will not hurt the radio.
I have restored several 520, 530s and 820s, all good radios with really good sensitivity.Better sensitivity than lots of new rigs.

John: Congrats on the purchases

Until Hurricane "Sandy" I was running an Off Center Fed (OCF) same or similar to a Windom with my '830 barefoot. Due to space restrictions, I could only run the 40m-10m version, but this thing really performs. There are some nice reviews on EHam...you can buy one or make your self...the only thing is that to do well it needs to be up a bit so that the coax feed can drop vertically down....say 25 feet. With the TS-830 and the pi tuning most of the time I didn't need my tuner.

At the same location, similiar configuration, it blew the socks off the G5RV! Unfortunately for me, with our recent move, my next antenna will have to be either inside the attic or really hidden,,,oh well.

PS: the Windom survived Sandy, but the tree didn't!

Good luck

Terry, I was able to squeeze a few minutes bench time today. I re-checked those voltages I gave you, and as you suspected they were incorrect. I'm not sure what happened. I used a different volt meter this time. Maybe there's something wrong with the "I got it free, with purchase" at Harbor Freight. Needless to say it's in the trash can.

I will label the (2) 6146 tubes as V1 & V2. V1 is the closet one to the front, and V2 is the closets tube to the back of the chassis.

Ok... here's what I did. I ran the rig into a dummy load, tuned it on each band as then checked the voltages on pin #3 on both receive and transmit.

Here are the results for V1. The first reading will be receive and the 2nd transmit.

160 meters - 267/225 VDC
80 meters - 267/224 VDC
40 meters - 267/225 VDC
20 meters - 268/211 VDC
15 meters - 268/70 VDC
10 meters - 266/140 VDC

And for V2:

160 meters - 267/224 VDC
80 meters - 267/225 VDC
40 meters - 268/224 VDC
20 meters - 268/218 VDC
15 meters - 263/68 VDC
10 meters - 264/200 VDC

Without really understanding all this, I can see that something looks a little funky on 15 & 10?

Leonard/WV3P

If you are just going to listen for now a LONG WEIRE will do. And it does not have to be straight. You can run it to a support as far from you SHACK as possible then bend it 90(?) degrees and run it to another support.

I live in a 20X20 RETIREMENT CLOSET near Seattle, I have a 40M dipole 6" below the ceiling. from the feedpoint it runs west 20' then north 20'. The other side runs north 20' then west 20'.

On last weekends contest I copied 2 Florida stations on 20M and 2 Japan stations on 20M. I copied a bunch of Midwest stations on 40M.

So until you are ready to try transmitting KEEP IT SIMPLE.

If you get a TECH ticket all you will needs a 10M antenna. They are small unless you want to put up a beam on a rotator.

Subject: [TS-520_820_530_830] Antenna for Ts-530s

Having just acquired the radio with matching ATU, an antenna is my next purchase. Currently due to licensing restrictions I can't TX so will just be listening for the time being.

Measuring up, I have 50ft in the back garden available to me for an antenna.
My choices so far are

G5RV(or similar), centre fed
Long wire, end fed
or
Vertical HF.

The G5RV might prove troublesome due to being centre fed as it the feed would be right in the middle of the garden and will get in the way
Long wire, would be the next choice with a 9:1 UnUn then fed in the AT-230 ATU

Or vertical HF.

As the ATU has 3 antenna inputs, 2 x SO239 sockets and 1 x wingnut type connector with what looks like a ceramic mount, I could run more than one?

As, I am only listening, could I just use a length of wire with a suitable connector at one end or use the wingnut type connector?

cheers

Do it the EASY WAY. Buy a Kenwood MC-50. Your TS-530 is made to use the TS-50.

Hi
Thanks for the info and reply regarding the mics etc. Looking in the manual the PO has written a diagram for the mic, as I think the socket may have been replaced at some point. Its now a 4 pin socket, with 4 circular pins (like my Rotel 240 CB radios has)

At the mo, I happy to leave the extra band/function in place.

Stand by for questions regarding antennas. I have seen G5RVs for sale here in the UK.

cheers

Subject: Re: New T-530s owner

John:
Good luck with your new radio.
It takes a high impedance microphone. Cheap old CB mikes work, Astatic D104s work, they are crystal, high impedance. Lots of mikes will work. Mike wiring diagrams are in the user manual.
I used a cheap Karioke Mike (600 ohms) once with good results, Xtal mikes are much higher impedance.

Your unit probably has a CB mod to 27 MHZ. 11 Meters.
If you want to restore to the original xtal sometimes you can find an entire oscillator board at a radio shop cheaply.
When I want to restore Xtals, I use Quartzlab, a UK company about $15 US an xtal. You might be able to sell the present Xtal to a CB shop and break even. Sometimes they may have your xtal that they removed.
But if you don't want to use 10 meters,ignore it.

Any antenna will work, a G5RV is nice because you can explore lots of bands, and since it is British, it might work best in the UK. Ha!.
Don't worry about any SWR, the Plate and Load will take care of it. I bought an antenna tuner and believe it is quite superfluous. It is better to have a good SWR but a bad one will not hurt the radio.
I have restored several 520, 530s and 820s, all good radios with really good sensitivity.Better sensitivity than lots of new rigs.

I'm an old G5RV fan. I've used them for over 45 years. However I keep getting puzzled by some of the results
obtained by (especially North American) users. Many years ago I frequently had QSO's with the designer.

G5RV himself rapidly found that the compromise involved with a match to 75 Ohm unbalanced could cause a lot of problems. In fact it was originally to 75 Ohm twin feeder!!!
Note UK TV used 75 Ohm coax or twin line at the time.
Later he always recommended that his antenna be fed through an ATU.

My present 102 ft G5RV is at 7 metres above ground and I can get out fine on everything down to 80 metres. Recently using it as a receiving antenna with a SDR radio I have designed, it works so well that I rarely use my Kenwood 820S unless I want to transmit.
I use a single coil Z match tuner with the coil carefully adjusted so that 2 bands don't coincide. This helps with rejection of out of band signals. The only band where problems can arise is 10.1 MHz where a small 1.5uH coil in series with one side of the open wire line enables a good 1:1 SWR.

So, when using a G5RV remember it is a balanced antenna. Open wire line can have quite a high SWR without excessive losses (unlike coax) and the feeders are an active part of the whole antenna, not just a way of connecting to it. Hopefully no one is trying to feed the end of the feeders straight from the transmitter output via coax!

Duff,

You say "nothing happens" when you try to dip the plate. What do you mean by that?

Do you see cathode current meter indication during TUNE mode tune up?

Did you remove the top cover to see if the PLATE shaft coupler may have broken or the coupler set screws have come loose?

What I mean is when I turn the alc to ip and flip send and move the plate around the reading stays at zero and doesn’t move.

Im new so I don’t understand the second question.

I have not removed the top cover. I have noticed that the plate knob will rotate 360 degrees. Is that normal?

Thanks
Duff

Duff,

You answered the second question when you said placing the meter switch to IP then flipping the SEND results in the meter resting at zero. The IP meter switch position displays the final amplifier's cathode current in transmit.

Check the rear panel's "SG" switch, it should be in the "ON" position. The SG switch is located on the rear panel directly below the fan.

Also, do you have the TS-820 operator's manual? If so have you spent time to thoroughly read the operator's manual so you become familiar with the various controls on the front and rear panel, what each control is for and how to use them?

Yes, the PLATE knob rotating 360 degrees is normal.

Forget about removing the top cover. Check the SG switch on the rear panel first.

I forgot the ask, do you have a 50 ohm dummy load that has a power rating of at least twice the power output of the TS-820 (250 watts or more)? If not then you need to purchase and use one. Tuning up on the air can cause interference with other stations on the same frequency.

Duff,

I don't have an 820 so I can't comment about the plate tuning control. On my 520, the plate control does have mechanical stop so its possible as Mike says that the shaft coupler screws have come loose.

Have you adjusted the idle current for the finals per the manual? Every radio I've had with tube finals is adjusted pretty much the same way.

You turn down the drive to zero. Usually this is controlled by the CARRIER control. On my 520 this knob is called CAR.
Key the transmitter.
Adjust the plate current to the IDLE current amount specified in the manual. On the radios I have this varies from 50mA to 100mA depending on the rig. This is controlled by a pot most often labelled BIAS. This sets the DC operating point for the final tubes.

Increase the drive level with the CAR control until the plate current increases above the IDLE current level.
Tune the PLATE for min plate current.
Tune the LOAD for peak plate current.
Peak the grid tuning for max plate current.

Increase the drive level with the CAR control and repeat the plate and load tuning until you either reach the max plate current specified in the manual or you can't get any more.

As Mike suggested, please make sure that you have read the sections of the manual that refer to tuning the transmitter. If this is the first time, do a dry run a few times with the rig off, imaging that you are getting plate current, just to get use to the process.

73,

Bill, WA6NEQ

Jim:

In the case of this KW Murata filter the simplest thing to do is just place a 2k resistor in series on each side of the filter. I experimented with placing the output resistor in series and in shunt and made little difference.

With no resistors you will see plenty of ripple. I didnt have any 2k resistors on hand so I just used a 1k resistor in series with test leads on each side of the filter and it greatly reduced the ripple that I had with no series resistance. If you want to get fancy can use a 3dB or 6dB 50ohm attenuator pads on each side.

Some fellows build a test jig and use a series trimmer pot and a shunt capacitor. This is closer to what the filter typically sees in circuit. So in this case would use a 2500 ohm trim pot and a 30pf glass piston trimmer. on each side of the filter. You adjust both for minimum amount of passband ripple. You test by injecting rf from the tracking generator (use as low a level as you can) in to one end and then reverse the filter and see if you have symmetry.

It just really depends on what kind of termination the filter requires. If it requires purely resistive then might need to place a small adjustable slug tuned rf choke in shunt on each side of the filter to cancel the stray capacitance of your test connections. I dont think this will be the case with any of the KW filters. I do want to be able to test any filter I should buy off eBay before installing it in the radio so I may build a test jig. Right now just using bunch of mini-grabber test leads.

Up until now all of my filter sweeping (BPF and Xtal IF filters) experience with KW hybrids has been using a Sweep Gen, RF detector, Freq Counter, and O-scope. So I am just learning how to use the Rigol DSA815-TG Spectrum Analyzer to do this same job. I normally only check the RX and TX BPF in the TS520 andTS520S rigs and the PLL BPFs in the TS530 and TS830 as part of alignment. I would not routinely sweep the Xtal IF filters unless the rig had a problem which indicated signal wasnt getting thru the filter or was being excessively attenuated.

To sweep the filters in circuit need to disable the VFO or the RIF in some manner as you dont want any signals coming from the receiver front end. Need the rig powered on so the filter switching diodes are biased on. I just connect at each filter switching diode cathode with a micro-grabber test lead.

Yes Sg switch is on. I also have the manual. I have read it and know the procedure. I have a pdf file of tuning instructions (NR6C). I ordered a dummy load and received it today. Today was the first time I have tried to tune it.

My elmer is not very familiar with these kind of radios. So that is why I am on here.

It looks like you are beginning to see something at 20 meters as well. I would shut rig down and make sure HV filter caps are discharged and line cord unplugged from 120vac recept and then measure R5 and R6 100 ohm grid stopper resistors.

I would also look at C11 and C12 screen bypass capacitors. Maybe they are getting leaky? Not sure you will be able to see anything with a visual so might just need to go ahead and replace them.

Also look at L2 470uhy choke to see if it looks discolored.

I will have to think about this some more as must admit have never seen screen grid voltage go down as you go up in frequency. The Xc of the caps is inversely proportional to frequency so higher you go lower the Xc so maybe they are leaky and it has greater effect as you go up in frequency?

Take a look at the parasitic suppressors as well to make sure the 47 ohm resistors in them are not burned up or cracked.

With the levels of SG voltage you are reporting the rig cant be loading up to normal output power on the higher bands especially 15 meters.

I have two OCF's, one that does 80 - 6m and the other 40 - 6m, both
without a tuner.
I bought the 4:1 baluns and did the rest myself, these antennas cost
about US$ 50.00 to make, thirty minutes to make and work great!!!
The 80 - 6 meter one's total length is 135 feet and the smaller one 68 feet.
I use the 80 - 6 meter one with my Yaesu 897D and Kenwood TS-830S and
the smaller one with my Kenwood TS-120S I have in the cellar.
I really like not having to use a tuner with either antenna.

Duff,

I don't have an 820 so I can't comment about the plate tuning control. On my 520, the plate control does have mechanical stop so its possible as Mike says that the shaft coupler screws have come loose.

Have you adjusted the idle current for the finals per the manual? Every radio I've had with tube finals is adjusted pretty much the same way.

You turn down the drive to zero. Usually this is controlled by the CARRIER control. On my 520 this knob is called CAR.
Key the transmitter.
Adjust the plate current to the IDLE current amount specified in the manual. On the radios I have this varies from 50mA to 100mA depending on the rig. This is controlled by a pot most often labelled BIAS. This sets the DC operating point for the final tubes.

Increase the drive level with the CAR control until the plate current increases above the IDLE current level.
Tune the PLATE for min plate current.
Tune the LOAD for peak plate current.
Peak the grid tuning for max plate current.

Increase the drive level with the CAR control and repeat the plate and load tuning until you either reach the max plate current specified in the manual or you can't get any more.

As Mike suggested, please make sure that you have read the sections of the manual that refer to tuning the transmitter. If this is the first time, do a dry run a few times with the rig off, imaging that you are getting plate current, just to get use to the process.

Ok so I bought this radio from a guy and he told me everything worked and it was bench tested. I just sent him an email and this is what he responded. "I generally tune for max power out. When there’s max power out the plate is dipped and the circuit is resonant. If you’re getting power out you need to switch the rig to read Plate current I think it’s called IC. But tune for max output that’s the real way to make it rock!”

Im not sure what he is trying to say but if I try to tune by the steps in the manual it doesn’t work.

Hi Duff,

Here is a quick version of the basics for the final tubes. This is generalized and not just for the Kenwood rigs.

The plate has a high voltage, typically around+ 850V to +1000V.
The screen voltage is typically in the +200V to +300V range.
The cathode is typically tied to ground though a very low value resistor.

The DC voltage on the grid is negative and controls the operating region of the tube. This voltage will often be called the "bias" or "grid bias". If its too negative, the tube will be cutoff and you will have no plate current. This voltage needs to be adjusted to a point where the tube is conducting and is in the operating region. This is what the bias adjustment(i.e- adjusting the idle current) is for and why you adjust it with no drive signal.

I don't recall the Kenwood values but I just recently was working a Yaesu with a pair of 6146B finals, basically the same tubes in the Kenwood hybrids. To give you an idea, in the Yaesu during receive the grid is switched to -125V, totally cutting off the finals. When you adjust the IDLE current to 50mA in transmit, the grid sits at around -65V.

The fact that you see NO plate current (Ic) during transmit suggests that you might have the bias adjusted for zero idle current.

"Ic" technically refers to the cathode current since that is what is actually measured. Cathode current is almost the same as the plate current.

Without getting into a lot of details, the seller is basically correct in that you can tune by watching max power out. However, you do need to max sure that you don't exceed the max Ic as specified in the manual.

Duff,

I mean no disrespect but I do believe some of the problem is your lack of knowledge and experience. Unfortunately there are many new hams such as yourself who get in over their head by purchasing a Kenwood Hybrid such as the TS-820 as their first radio. Those new hams tend to lack the knowledge and experience to properly and safely operate these type of radios.Kenwood hybrids are not plug and play radios like modern day radio are, they require adjusting/tuning the controls in order for the radio to operate properly. If this is not something you are willing to do/accept then a Kenwood hybrid may not be the radio for you. You may be better off purchasing and operating a modern Plug and Play radio instead. Again, I mean no disrespect, just pointing out areas you may not have considered before you purchased the TS-820.

Good luck and congratulations on passing the General exam.

Take a deep breath and take some time to get comfortable with the 820S. I bought an 820S new when I passed my general and I still have it and love that radio. It took a little time to get familiar with tuning the radio, but after a little practice it is easy to do. There are people here that will walk you through it. It has great transmit audio an receives well. I have worked tons of DX with mine. It was foreign to me when I started but soon I was on the air and making contacts. There is a lot to learn about the radio and making an antenna system work for you. Not too much of a challenge but lots of fun. Good luck on your General an success on the air.

Duff, the video didn't make it. You can send it to my e-mail address, my call at yahoo dot com.

One thing I noticed is, you said the IP meter indicated zero when attempting to adjust the PLATE control for a dip. Now you say the IP meter indicates 60ma of idling current.

I recommend you have a look at Terry, K9TWs, website

www.k9tw.com http://www.k9tw.com

Click on the "HOW TO GUIDE" and follow the tune up steps on how to tune up a KW hybrid. Ignore the name "Peter", replace it with "your name".

Duff....I don’t remember what your original post stated as your issue...I think it was no meter movement? (At least, that’s what I got from the video) do I vaguely remember running into that issue with one of my early 820’s. Unfortunately, I don’t remember the solution, but I *do* remember it was an easy fix...Yeah, yeah...I know...easy for me...Nope...it truly *was* easy.....

Hope you can get it sorted out...The receiver is one of the best of the older radios....Don’t use mine all that much any more...Pretty well stay with my Drakes now, but the both my 820’s (one an ‘S’ the other a normal) get fired up periodically to keep them ‘sharp’.

Mike:

I need to add a statement about how to load in CW mode when it appears R5/R6 56k appear to be open (assuming SG switch is in ON position and is good). Just makes me a little nervous about telling new person how to "fly with the governor bypassed"!

As soon as I can find the time I will make a loading video and post it. I searched Ebay hoping to find a decent one to refer new folks to and very sad to say most are poor and some just flat wrong.

I hate it when someone flips to Send and then takes half hour to adjust the focus and lighting! OR I hate the discussions about how important it is to keep ALC in middle of black range and go back and check it and re-adjust it! OR I hate those who move the Drive control and/or Plate Load control as if they are level controls! Some of this is demonstrated by extra class holders. Fortunately the rig is pretty robust and you have to work to hurt it.

Terry,

Yes, I agree, kinda hard to take telling a newbie how to tune up a KW hybrid in CW mode especially if the person has no experience.

I now see Duff said he has 60ma idling current in sideband, something that was questionable before. That's what was confusing me, first there's no idling current then there's idling current then the video shows no idling current. Now he says he has 60ma idling current in sideband. I'm going to assume the 820 has 60ma idling current in USB or LSB mode.

Duff, have you elmer check the 2 resistors R5 and R6, on the HV Unit. They both are 56K 1/2 watt and if they are bad then you will experience this problem.

You will need to show him the 820's operator and service manuals. If you do not have the 820 service manual, you can download it at my website

www.w5rkl.com

in the manuals and documents page.

Duff,

I see you have found both R5 and R6 on the HV Unit board to be bad. You can probably find those resistors at Radio Shack, they are 56K 1/2 watt resistors. The color bands around the resistors will be

GREEN BLUE ORANGE and maybe SILVER or GOLD as a tolerance color

GREEN is 5
BLUE is 6
ORANGE is 1,000

Therefore GREEN/BLUE/ORANGE is 56,000 ohms with either SILVER or GOLD tolerance band.

The tolerance band colors are

SILVER = 10%
GOLD = 5%
No color band = 20%

If you plan on performing any service to your ham gear you need to learn these things. You also will need to learn basic electronics and you won't learn that by simply asking a few question. You will have to spend time, a minimum of an hour a day, studying basic theory. You will also need to learn basic vacuum tube theory. You can down load a very good vacuum tube theory book, pdf format, from my website's Manuals and document's page, titled,

"Inside the Vacuum tube"

Vacuum tube theory is also provided in the Tube Manuals I have on my website so feel free to download them as well.

Also look for older editions of the ARRL Handbook, 1968 or older editions.

Another good book, my favorite,

"Basic Radio Course"
by John T. Frye

This book is out of print but you can find it on the web, sometimes "used" at Amazon.com. There's an seller on eBay selling the 1951 edition on a CD for $9.99. Well worth the price. You also might look at used book stores and your local library, either place may have it. I have the 1961 hard cover edition plus I bought the eBay seller's CD. I compare both copies and found the only difference between the 2 are

1. The eBay CD edition doesn't have the solid state transistor section
2. The make and model of the test gear is different/older than the 1961 edition

Duff:

Just make sure your Elmer helps you replace both of them. It is common for one to go open or very high and the other to measure OK, but it is good practice to replace both while you are there and I would use Metal Film or Metal Oxide and not Carbon resistors.

From: louis.wilen@...
Topic: 48907 Message: 48907

Quick question about the alignment instructions for a TS-530S:

Alignment step 5, VFO, RIT check and adjustment. This step says to connect the RF VTVM to "Pin 1, connector 6, 2P (GND)". I understand what "Pin 1, connector 6" means, but I'm confused about "2P(GND)".

What is "2P(GND)"?

Louis

Just ignore it. It means that the No 2 or center pin of Conn 6 is ground point they are using for this measurement and adjustment. On the TS-830 they show 1P(GND) for the ground connection. You can read any ground point including chassis ground and it wont make any difference on reading the VFO output level on the PLL board.

Ordinarily for measuring RF voltages on the various PC boards good practice would be to use a ground connection as close to your measuring point that you can. Most RF millivolt meters supply a probe tip that has a ground prod close to the measuring prod (almost impossible to use them due to component density) and usually also have very short ground leads. This is because they are capable of measuring high frequencies, but at the frequency of the TS530 VFO this is not critical.

If you look at my website will see how I removed the factory short ground lead on my Boonton and added a more practical ground lead since I am not making any RF measurements above approx 30mhz.

In my personal TS830s I have also installed some additional grounding points. In some cases can do that without lifting boards and installing them at thru hole spaces available on the board ground plane by using old fashioned solder lugs bent at angle. Place them under the board hold down screws and will have a nice place to clip mini-grabber test lead. I do it as matter of convenience and not so much to worry about accuracy or mv differences in the ground plane.

The output should be set to 200mv +/- 1dB which means 178mv to 224mv rms.

You can set it to 200mv and then move your RF probe ground lead to various locations and repeat and should see no appreciable change in voltage reading.

Congratulations Duff for fixing your 820. You might want to jot down this fix so you will have it for future reference. It's easy to forget. I'm 65 years old and I forget what I did to fix a problem I experienced before. I think they call that a "Brain Fart".

Remember, tune up into the dummy load FIRST then switch to the antenna.

You don't need an expensive antenna to get on the air. Try 40 meters, it's open all the time. A simple dipole cut for the middle of the band then trimmed for the lowest SWR will work fine. If you don't have much room, mount it as an "inverted vee" strung over a tree limb. Get it as high as possible. I use an inverted vee hanging from a pine tree limb, 25 feet above ground, fed with RG-8x. SWR is 1.2 to 1 and I work almost any station I can hear, even Japan early in the morning. I operate CW on the low end of 40 at 90 watts from a Drake B or C Line, no tuner, connected direct to the antenna. You don't need a lot of power. The most important item in your ham station is your antenna. You can feed 1KW into a bed spring and not talk beyond your state line but feed 25 to 50 watts into a well designed antenna system and you will work DX and lots of stateside stations than you can handle!! I operate low power on 40 with a Heathkit DX-40/HG-10B VFO and an SB-300 receiver. The DX-40 produces about 40 watts to the antenna and it fun working low power. I also work low power on 10 meter AM, 29.0Mhz using a Johnson Messenger 223 I converted to 10 meter AM and changed it to VFO control (N3ZI DDS2 VFO). I worked Italy earlier this year before the band bit the dust using the Messenger 223. The antenna is a simple home made 10 meter inverted vee up about 20 feet.

Once you get use to tuning the 820 you'll be tuning up much faster.

Duff:

I dont mind so much getting forgetful in my old age (37 my next birthday!). What I do mind is finding out that things that I knew with 100% certainty to be true turned out to be false! Pity the poor Flat-Earthers!

In your study of fundamental electronics and basic radio communications you will have to accept some things on faith and it may take years before you have an "Ah-hah" moment.

The other thing I hate is to see people (supposedly knowledgeable and experienced) demonstrate something wrong and do so in a very confident manner! See this on You Tube. Like all info on the internet it is a challenge to sort out the good from the not so good and the just plain wrong. For my money you will serve yourself well if you come to this Reflector for KW hybrid help. If someone bum dopes you here there will always be someone to challenge it in professional way. This is not an easy medium to troubleshoot a technically complex machine. Understanding what the person is seeing and reporting is often about half the battle.

With the attitude you have expressed all you need to complement it is interest (better yet passion), a questioning attitude, work ethic, a little aptitude, and 50 more years! OK maybe not that long, but point is it is a life long pursuit and takes time. I am 50 plus years in the hobby and over 10 years a KW Hybrid repairman and still learning.

Of course if you intend to be your own repair man then along the way you will have to start building a modest test bench (starting with VTVM & rf probes, RF Sig Gen, and Freq Counter).

Just be very careful under the hood of your TS-820.

Have Fun

Wally, I have been playing with the Oscope and got about 20mV on TIF using the .1 microsecond setting on 40 meters. I don't see OSC on the RF board. Is that OX or OL perhaps? Separate question... In double checking R5&6 on HV board (seeing 65K and 82K - going to replace them) I find R7 which is a 12K across TUN and 210. This doesn't show up on the schematic. Do you know if this was an add-on for a later release? Serial # 360268. Thanks, Charlie - AC6ZX

Charlie:

Not trying to step on Wally Docs thread, but it appears you are trying to run the TX Level Diagram and may be stalled waiting for a response. My bench is cleared until Monday so here is my 2 cents worth.

Are you following the Figure 14 procedure in the Service Manual? Normally you would load to approx 100 watts out at 14.175mhz and then turn off the SG switch and take the rf voltage measurements. If you cannot load to that level then load as high as you can and proceed.

The next place to measure TIF signal is at TP-2 on RF board. You should see approx 250mv rms at TP-2. If you have TIF to the RF board very unlikely will not have it at TP-2. Can be low if someone has messed with T1 slug. After that move on to MD. This is the output of the TX Mixer and the first place where you will see actual transmit output frequency. This is the rf drive that is applied to the control grid of the 12BY7A driver tube. At MD should see approx 2.0 to 2.5rms volts of rf drive or 5.6 to 7.0 volts Peak-to- Peak on your O-scope.

There is no RF board test point labeled OSC?

I suspect Wally Doc was trying to direct you to check the LO (local oscillator) level to the TX Mixer? The Het Osc provides the LO signal for both the Rx and Tx Mixers. No LO signal means no RF output from the TX Mixer. This does not happen often.

Assuming he was trying to direct you to the Het Osc you can measure the output at TP-3 on the RF board. It will be around 1.0 rms volts and rare for it to be missing on all bands. Common to be low or missing on 1 or 2 bands due to someone setting the Het Osc coils on the fast side of the response curve peak. If you do that the oscillator may not start reliably. I wouldnt mess with Het Osc unless you are doing an alignment or you find you have no RF drive at MD on a particular band. If you find the Het Osc level is good and no RF drive at MD then need to take DGGS dc voltage measurements at Q3. Seldom for the dual gate mosfet to fail, but can have problems with switching bias. If Source lead measures close to Drain then device is shorted.

As for R7 are you sure the rig you have isnt a TS520S? OR maybe someone swapped HV unit boards?

48920. HYBRID NET UPDATE (June 1, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-01 19:18:28 UTC
From: Mark Gilger
Topic: 48920 Message: 48920

```
Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday□s net was run by, me, WB0IQK. There were 19 stations checking in under good band conditions. We had the following number of radios checking in.

```
2 running TS-520(x)
4 running TS-530(x)
2 running TS-820(x)
1 running TS-830S

The reset were running non Kenwood hybrid equipment.

I was running his TS-940s and my Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in under poor band
conditions. We had the following number of radios checking in.

3 unning TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
1 running TS-510

The reset were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).
```

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82

48922. TS-520 Pre-emptive Maintenance?

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-01 19:28:31 UTC
From: WQ8Q
Topic: 48922 Message: 48922

I'm new to the Kenwood hybrid game, (and this forum) but not to radios. I managed to ruin a few Heathkits back in the day.

I picked up a "non-working" TS-520 at Dayton. The rig looked as if it had just been sitting on a shelf in a shack for a long time.Except for the first few letters of the name Kenwood being half rubbed away, there is hardly a mark on it.The phillips screws weren't even boogered up -- they looked like they'd never been removed!Brought it home and hooked it up. I got it to receive somewhat scratchily by wiggling the bandswitch.

I took DeOxit to the bandswitch and all the noisy controls. Cleaned and lubed the fan and blew out the interior. Then the receive worked just fine.Tried to tune up into a dummy load and had a problem there . . . took out the relays and cleaned them and more DeOxit.Everything tuned up just fine.Full power out on 40 and 20 (which is all I tried).Everything looks good on the SM-220 (which I also picked up in Dayton -- in its original packaging!Now I've got a total of $150 invested in both pieces -- you can make good deals when it's cold and hail is falling)

So, I've been using it for a week on CW (sideswiper) and SSB (MC-60A) and getting great reports. I even checked into the Saturday Kenwood Hybrid net. I'm having so much fun that my Elecraft K2/100 I built ten years ago is now sitting lonely on its own little shelf.

So, here is my question:Leave well enough alone and keep operating?Or investigate a little further and maybe change out the big caps?Pre-emptive maintenance?Anything else to look for?

> caps?Pre-emptive maintenance?Anything else to look for?

You've DONE the 'pre-emptive maintenance.' DUDE, leave it alone!

Here's to a great deal on a fantastic rig. You done good. No, GREAT.

If the thing has a full 100 W out on all bands, and receive is clean, you're getting good reports on the signal quality, then the WORST thing you can do is to open it up and fiddle.

Have you gotten all the documents for it? The service manual, the owner's manual, and a high-resolution scan of the schematic, for when something does go wrong? Get those, peruse to familiarize yourself, and enjoy the great deal you managed to grab. These beauties are going for three and more times the price you spent total.

Be thankful for your fantastic luck.

Rick,

You sure did score!
You have cleaned switches, pots, bandswitch wafers..etc....rig sounds like it's working good...let itbe...but with one observation: keep an eye on the high voltage reading. Anything more than around a 10% drop in HV... when keyed (CW)..may indicate weak/failing HV capacitors. You should see around 750+VDC at max output. I take it that you inspected them..to see if they may have started to bulge, or worse...leak.

Other than that...use it and have fun!

Charlie: Do you have signals at TIF and at grid of the driver?
TIF freq.should vary with VFO.
Is the signal at grid of driver (pin 2) the proper RF Frequency? This should vary by band and VFO tuning. It is your transmit freq.
What is the driver output? pin 7, DP and DRV are all driver output. This goes to the final grids and can be measured there also.
Driver output should be a big signal, 10-15V Peak to peak, if I remember correctly
Scope should be on AC, please.

Let me know.

Rick: The advice everyone is giving you is correct.
Leave the electronics alone.
Read this group from time to time.
Make some notes on where to get parts, esp big caps. Sometimes you cannot get the originals, but there is room in the chassis to put replacements.
Maybe pick up some spare tubes at a hamfest, I picked up perfectly good used finals for $5 each.
Read something about the various tubes available, and make up your own mind first.
You may want to experiment with different higher impedance mics, another hamfest acquisition, along with a few four pin connectors. (I picked up a Heil dynamic mic for $5).
If you have to do something put a drop of oil on each retaining screw on the knobs, in case you have to remove them at a later time. If you get good output and no carrier on SSB, the thing is aligned fine.

Wally Doc

This really pains me and frankly frustrates me and makes me a little angry that I am the only one willing to speak up. I dont understand why everyone else sits in silence? We are not talking nits here. This goes beyond using the correct trade parlance.

I am trying to be nice to you, but you make it very hard. We have had this discussion before and I try to do it in a non biting manner. I really should not have to do it at all. However, I cant just sit here and let you bum dope Charlie. It also puts Charlie and others like him in a hard place to be in the middle of sorting out good counsel from not so good and from the flat wrong.

Your counsel goes far a field from just being a problem with "nomenclature". This is NOT about meeting my expectations or standards. This is a technical forum and I am proud to be a contributing member. We can all make mistakes or have typos from time to time, but what you present goes beyond that.

1.There is NO Transmit Intermediate Frequency (TIF) signal at the control grid of the Driver Tube. You will find no 8mhz at control grid of the Driver tube. There is actual transmit frequency at the control grid of the 12BY7A driver tube. The transmit frequency that is indicated on the VFO dial.

2. There is seldom any reason to measure the frequency of the TIF signal when troubleshooting loss of rf drive or low rf drive. I cant remember last time I had to do that. With the VFO in middle of range and you measure TIF rf voltage level and find it to be within spec you know that the TIF frequency has to be very close to 8.595mhz.

If Charlie had no or very low TIF signal level at the input to the RF board then he would go back in the chain and measure the rf voltage level at the input to the TX Band Pass Filter (BPF) on the IF board and if he had TIF signal there (approx 600mv) then he might suspect someone had grossly mis-adjusted the TX BPF coils. That does not occur often.

Charlie has already reported he has approx 20mv of TIF at the input of the RF board. That means that the TX Band Pass Filter (BPF) is tuned reasonably close. If he wants to see what his rf drive signal frequency is at MD test point and has no frequency counter he can listen to it on a separate receiver and see if it is close to where his VFO is set. There really is not much need to do that at this point. He needs to run TX Level diagram and where he finds RF drive voltage does not meet spec then see if he is missing a LO signal or if the dc voltages are wrong at an active device.

3. Wally there is absolutely no reason for you to provide RF drive levels from your memory unless you are an experienced KW TS-520 repairman. Experience would tell you that you would never normally expect to find 10v to 15v P-P at the plate of the Driver tube. The Service Manual TX Level Diagrams should be consulted as I have already mentioned to Charlie. The RF drive at the control grids of the finals should be approx 46.0rms or 130v P-P and the RF drive voltage at the plate of the 12BY7A driver tube should be approx 58.0rms or 164v P-P. You are off by an order of 10x.

I have these values burned into memory from having done very large number of rigs, but I seldom quote them to anyone from memory. It only takes a minute to consult the Service Manual or your notes to confirm what a design parameter is. In addition to note books I use a 3x5 card file with things like RF drive levels, Driver Tube dc voltages, TX Mixer dc voltages (actual measured values from properly performing radio).

Wally this is last time I will attempt to help you. I challenge the rest of you not to just sit on the side line when technical direction being provided by anyone is not correct. We all owe it to Charlie and other new KW hybrid owners who need the help. We also owe it to Wally.

When I bum dope (and I have) I expect someone to question and challenge. If that does not occur then what is the point of this group?

Thanks for all the advice, guys . . . I guess I had better leave well enough alone, although I will keep my eye on the HV meter and make a visual inspection of the HV caps.

One thing I did discover - I dug out an Idiom Press SCAF filter from the closet and hooked that up between the TS-520 and my go-to Ten-Tec 307 speaker and that really cleans up the QRM, especially on CW.
And, just for fun, I plan to use the 520 in this week's SKCC weekend sprint.

Rick, do you have the optionl CW filter. I ordered my 400 HZ Kenwood filter the first day I had my new TS520 home from the store ! Working CW with the SSB filter, at least for me, was near impossible when the bands were open !!!!
I Added the outboard Autek Research QF-1 filter next and that was worth it's weight in GOLD !

John, I found a CW filter for the 520 and it will be here this week . . . so between that and the SCAF filter I should pretty much have things in hand.
I love my K2/100 (loaded) that I built, and I'll probably never sell it because I built it, but the little knobs and buttons aren't that much fun and I really don't like the sound of DSP processing that much. Sort of an old school guy I guess.
One thing you may find amusing, in the original TS-520 QST Review (Sep '74) the author says: "Placement of the various controls proved both convenient and comfortable for operation. While some are very closely spaced on the front panel, no difficulty was experienced in using the system."
I wonder what he would say about today's rigs.

Rick,

I owned a TS-520S in the early 80's with a CW filter that was sweet. The filter makes a huge difference. Good luck with yours.

I just got out my TS-830S after being in mothballs for the last 14 years. I purchased it new in 1986 and it still puts out an excellent signal with the original tubes.

Topic: 48922 Message: 48939

> ... after being in mothballs for the last 14 years....

I'm not hoping for replies, not to the list anyway. Just some thinking.

I keep seeing similar postings, time and again, on this and several other radio lists and forae which I read.

"I have eight other radios in storage...."

"... only pull these three radios out about once a year each, to blow the dust off of them...."

"The other five rigs I don't use any more, they've been in the closet for about ten years now..."

Being the country mouse here (and almost everywhere else in the Ham world) I congratulate you all on your obvious good fortune and financial acumen.

But I am forced to wonder a little: Just how many NEW hams would benefit from the CONTROLLED and CAREFUL loan of one or more of these dozens and dozens, hundreds without a doubt, older radios, along with the mentoring which could come along with it? If you so chose?

I know the statistics show more licenses now that the FCC has watered things down to cater to the least common denominator. But that doesn't mean that some of us can't try to force that "least" level up a few steps, at least locally.

Just a thought. If you happen to have a radio you're never going to use again, please consider other options than selling it on e-Bay or out of the tailgate of your pickup truck to a complete stranger from perhaps all the way across the country.

Nothing wrong with being from "across the country," don't get me wrong there. Nor in selling used kit at a profit.

But is there possibly some punk kid in your home area, who would dearly love to get involved, but just can't make the piles of wonga needed to buy new equipment? Maybe sell it on terms over time, and teach the punk how to use it?

Could be a good time at an antenna party and barbecue later, when the punk gets his ticket. We used to do that for people when they upgraded, come over for a small bash and help run in the new antenna or three (multiband trapped long-wires are easy enough to make) so they can use their new license privileges. After they get the rib grease off their fingers, anyway.

I wonder what ever happened to that habit?? Ticket upgrades used to be a great excuse for a party. A new Novice license was always a great reason for some creative kit bashing and a lot of good food and camaraderie. (It lets all of the non-ham spouses have a chance to compare notes, too. Expect new ways to be lambasted for DX-ing instead of mowing the lawn or fixing the faucet.)

Or if you have a perennial complainer next door, get your neighbour involved instead of ragging at you for your antenna farm. Gift the griper with a radio (or sell it reasonably after you've loaned it to them, and they're hooked), and Elmer them right into being your Field Day partner? Or if they decide they don't like it after a good exposure, at the least you will have tried, and they might moderate the complaints now that there is some basis for understanding. Or maybe not, but at least you tried.

Just a few thoughts about a seemingly huge amount of perfectly good gear slowly going to wrack and ruin for lack of use.

Oh, and I just got the word that the 4-H Ham Club here is now a definite "GO." The state investigations somehow missed the decades I spent as a serial axe murderer, and have approved me to work with kids with the 4-H and county extension office. SLOWLY the wheels turn, but they grind exceeding fine.

Looks like I'll be Elmer to a maybe dozen kids, more or less, starting about next September.

And I'm starting them off on TUBE RADIOS. My 520SE is going to get SUCH a workout.

(It's too late to do more than give them a quick heads-up about it this school year, maybe get a few names together and look for parents to help out. I have to wait to get the ball really rolling until next school year starts in late August/early September. That gives me time over the summer to make the meeting plans and get the rest of the odds and ends together for them to start learning on.)

Do-as-I-say?? Nope. Do as you feel you ought; this isn't a "shame on anyone" kind of note. I am going to avoid any accusation of hypocrisy and point out that I -am- doing as I say, or trying to anyway, at the best rate I can manage. You-all do whatever makes you happiest.

But me, I just think there has to be someone trying to drag the next generation off of their video game consoles and into -soemthing- with a little meat on its bones.

I'm just hoping at least ONE person on this list gets the bug and tries to spread some of their knowledge amongst the savages which are some other peoples' offspring. (Even just one could make a world of difference. You never know who is listening, or what they'll make of it.)

Rick,

I don't do any work on 520s\820s, but mainly work on the 530s and 830s. This is what I do for every new radio that I buy or that comes across my work bench, it is not a recommendation but something to ponder.

Apart from normal service faults or cosmetic restoration, every radio gets a new set of HV caps, I take measurements on various key areas and inject signals and see where the selectivity and sensitivity is at and make notes for the future. I also replace relays etc as I know from experience that relays will start to create issues, deoxit and dry air is a must for all radios, so even if you chosse not to change anything, get them and have them on hand so you dont have to wait. I buy the majority of my stock from Ken K4EAA, hardware parts\boards from Bob KE5FTF. I use a good quality light oil for the fan. From past experience I also spray the various rear panel din plugs and exercise to make sure they aren't stuck or building up corrosion. I have been known to polish the octal plug pins. It really depends on what your comfortable doing without causing any problems. Mark,Mike, Terry and Joe along with others have outstanding knowledge relating to this series of radio.

Welcome to the work of the Kenwood Hybird.

73s

Dave

Tony,

There are a couple of battery powered external ALC control circuits in the group's website under "Files" that will reduce power output from the TS-820. Using this circuit you will not be able to connect the 820's external ALC connection to the AL82 ALC connection.

Why are you wanting to reduce power output from your TS-820 when connected to your AL82 amplifier? If you tune the 820's transmitter and make the MIC gain adjustments properly, keeping the peak 820 ALC meter indications within the 820's ALC meter scale and you follow the amplifier's tune up instructions and follow the amplifier's ALC pot adjustment instructions in the amplifier's operator's manual then you shouldn't have any problems using the TS-820 with the AL-82 amplifier. You simply make the connections between the TS-820 and the AL82 as shown on the AL82's manual INTERCONNECTION page.

You will need an 8 pin octal plug to connect the amplifier's RELAY and ALC connection to the TS-820.

The AL-82's RELAY is connected to the TS-820 using shielded cable at the TS-820's REMOTE 8 pin socket on pin 5 and the AL-82's ALC is connected to the TS-820's REMOTE 8 pin socket, also using shielded cable, to pin 6. Ground on the TS-820's REMOTE socket is to either pin 1 or 4. The AL82's relay voltage is 12VDC at 100ma and the TS-820 amplifier relay terminals can easily handle that voltage. You can use cheap stereo shielded interconnecting cables, those cable you find in DVD or VCR players/recorder. You can also use a short length of RG-174 coax cable. A short piece of RG-8x will do fine to connect the TS-820's output to the AL-82 input.

You may read elsewhere, not on this group, or be told by hams elsewhere or on other ham forums, that power output can be reduce by adjusting the LOAD control on the TS-820. DO NOT follow that ill advice!!! Also DO NOT adjust the TS-820s DRIVE control to reduce power output either!! The TS-820 should be tuned up for maximum power output and the MIC gain control set properly as discussed/shown in the TS-820's operator's manual as well as following all the tune up instruction in the AL-82 manual.

Go to Phil Salas AD5X website under Articles and see how to build a simple 3dB T-pad attenuator from inexpensive thick film resistors. Can be manually switched or relay switched. Using inline attenuator allows you to retain ALC input from the amp.

Actually the receiver has enough gain that you probably would not have to switch it out in RX mode.

The simple manual switched unit is toward the end of the article built in a small bud box.

Good morning, I agree with Terry. I made the same choice with my 830S. I have a 811 amp and tried several different acceptable circuits, I chose to use Phil, s design for the simplicity. You can calculate any drop you choose but I used 2dB as it attenuates my 830S to 65 watts. That drives my 811 perfectly. Word of caution : Do Not skimp on the resistors. Use the correct wattage for your calculated power. Follow Phil's notes. I think you will enjoy the results. Mike's counsel is also good advice but I did not want to fuss with my 830. Besides, you can use the attenuator pad on any rig you choose. Have fun with your 820. Best 73 to all. Don K5HFG

Hi Dave and Rick:

I have resisted responded due to pretty much always being the odd man out!

Depending on the TS520 owners knowledge and experience there are several questions they should ask:
1. Is there any thing I should look for (correct size fuse, swollen or ruptured filter cap vents, cracked RF Plate choke bypass capacitor etc) or measure before I power the radio? Should I just fire it up or should I soft start it (variac or dim bulb method).
2. Is there any preventive maintenance that I should perform (Ricks question) ? Or spare parts I should buy?
3. How do I know if my receiver and transmitter are performing to design spec? Are there any simple operational tests I can perform to assess the receiver and transmitter performance?

I agree with you regards replacing the HV filter caps even if they ESR and Bridge out OK. Eventually they will fail and they often cause collateral damage. Re-oiling the fan bushing holder felts is good practice as well. I also clean the Aux and Ant TR relay contacts on the older series units and generally replace at least the Aux relay on the TS530/TS830 (now using Kens new design) as cleaning the contacts is not easy or long lived. I also clean all the air variable capacitor rotor shaft wiper contacts, and I lube the VFO gear train with Tri-flow. I also De-0xit the bandswitch contacts and all accessible pots and switches. Of course a good visual inspection and blowing out all the dust including the PA cage. That is about it.

I dont know anything about Ricks knowledge and experience so my comments are more directed toward a newly licensed ham who has purchased a TS520 as perhaps a first HF rig. If you have never owned one you really have absolutely no point of reference as to what constitutes "good" receiver or "good" transmitter performance.

Yes there is something to be said for the If Not Broke Dont Fix It Approach, but "broke" is defined differently by different people. Anytime you go into any of these old treasures to perform preventive maintenance you do so at some risk. Been many a molex connector pulled off a board. Been many a ferrite slug cracked. Easy to break something or induce a latent fault that will come back to bite you later.

With that caveat in mind I offer this specifically to a TS-520 and with direct correlation to all the hybrids:

How do I know if my TS-520 receiver and transmitter is performing at or near factory design specs?

1. All of the owner operator instruction manuals have the receiver and transmitter specs listed near front of the manual. Problem with that few hams have the test gear, knowledge, or experience to measure the listed parameters.

2. Assessing the Transmitter performance is a little easier. Can you load to approx 100 watts out while not exceeding 200ma plate current with exception of 10 meters where 80 to 85 watts is normal? You can obtain on air signal reports of signal strength, audio quality, and audio punch. If you get the right person can also get some idea of how wide you are. Better yet lots of folks today have panadapters and can look at signal bandwidth for you. Also, it is very easy to test the Driver stage by turning off the SG and peaking ALC indication in CW mode. Should be able to obtain full scale deflection with CAR level advanced no more than 1000 to 1100 with exception of 10 meters which will take more CAR level and wont attain full scale deflection and NO it is not normal to have no ALC indication on 10 meters that forces you to use work arounds to load on that band.

3. Best method for assessing the TS-520 receiver sensitivity is to use a calibrated RF signal generator to inject known levels into the SO-239. Lacking that test gear then sensitivity testing can be done simply by employing A-B testing if you have a commercial ham rig like a Kenwood or Yaesu or Icom etc that is unmolested. Simply go to each band and select a weak signal to copy and switch antenna back and forth between the two rigs and compare copy. If you have no other receiver you can use your Marker signal (25khz xtal calibrator) and S-meter for a rough test. Go to the Maintenance Section 6 of your manual and set your VFO per the Band and Frequency chart and tune to the Marker and peak it with the VFO and Drive control. You should see approx S8 to S9 on all bands with the Drive control peaked at approx 1200 position. Again S-meter indication will be lower on 10 meters perhaps S5 to S6 level. This of course depends on if previous owner has not "calibrated" the S-meter. If they do they usually make it more generous.

Now what if your receiver sensitivity or transmitter ALC indications and rf output does not meet the above results or is grossly off? Well that is why KW provided Sect 6 in the instruction manual. It allows you to perform a pretty good alignment without the aid of test equipment. However, KW never intended for owners to be performing alignments on some routine schedule.

Typically it wont be too long before a new owner wants to perform a coil pack alignment regardless of how well he feels the rig is performing. I dont recommend alignment as a routine and certainly no substitution for systematic troubleshooting. Alignment comes with risk. Risk of damage and risk of wearing out the adjustment trimmers, coils etc. Almost every KW Hybrid you buy today will have gone thru many hands and many folks under the hood with golden tweakers so it is natural to want to re-baseline your rig at some point. A well done Sect 6 alignment can put the TS-520 receiver and transmitter in very good state of trim.

If you perform the simple operational tests noted above and find performance to be down and decide to perform a coil pack alignment and IFT/RF coil alignment on your TS-520 you must do the following:

1. Under good lite and magnification inspect all of the ferrite slugs on all the coils on each RF hanging board. It is very common for these cores to be cracked. If you insert hex alignment tool in them and turn the tool you will spread the crack and only cause core to resist turning. Cracked cores have to to be removed and not an easy task. Often best to just leave as is unless it is a Het Osc coil which is grossly misadjusted and oscillator wont start reliably.

2. Use a proper plastic hex tuning tool. Ken K4EAA sells proper one on his website.

3. You can apply a drop of lubricant like WD-40 at top of the core with pointed end of toothpick in attempt to free the core. Typically not very successful.

4. Can apply heat from the tip of small soldering iron to the core. Must be done very carefully.

5. If the coil former is found to be cocked or torn off the plastic mounts leave it alone or be prepared to pull the hanging board and replace it.

So yes it is often best to just leave your TS-520 alone if it is working "good enough". Problem is if you have a new to you TS-520 and have no experience with it or any HF transceiver it is hard to define "good enough". My post is an attempt to define "good enough" receiver and transmitter performance. You should have noticed I confined my remarks to receiver sensitivity and not selectivity. That is a subject for another time!

Terry K9TW

48945. OK, the rig works, now for the antenna

Yahoo group: TS-520_820_530_830 (2014)

Now that my "new" TS520 seems to be working pretty well I'm lookin' for some ideas on antenna erection.

I am trying to get a line up over a tree branch so that I can pull up one end of a long wire antenna in my back yard. I have made the conscious decision to keep all of my 67 year old body parts right here on terra firma, so using a ladder is out of the question. Besides, I don't have one long enough and even if I did I'm really not interested in wrestling it out of the garage, up into position and then back into the garage…where would the challenge in that be?

Plan A (executed this afternoon) - This involved using a slingshot to lob a large, heavy nut tied to the end of a string up and over the branch so that I could begin the process. Despite the ill-conceived nature of the plan, large portions of this plan actually worked quite splendidly. Apparently, my many years as a mischievous teenager were not at all in vain, after all. It took a couple of tries, but I was easily able to successfully place the nut (with the string attached) over the several of the suitable limbs…there were about 4 possibilities.

Unfortunately, the nut wasn't heavy quite enough to overcome the friction of the string on the branch so despite my enthusiastic tugging and jiggling, I couldn't persuade it to drop down the opposite side to complete phase 1 of Plan A. You "may" actually have heard my "mutterings" even from wherever where you might have been at the time.

So, on to Plan B - My latest thought is to beg, borrow, steal or fabricate…notice, I said nothing about purchasing…a "stick", for lack of a better term, with which to gently lift the nut over the desired branch and then reach up, grab the little sucker from the other side and yank it down. The problem, of course, is the the length of said stick will need to be at least 25' and preferably 30' long. It won't have to have to lift much weight, but I recognize that keeping something like that stiff enough to use without making it heavy or expensive to build may be problematic. I will probably be able to rest it against the tree on the way up, so even a somewhat floppy stick may suffice. Hmmmm….as I write this, I realize that by using the stick I "may" be able to use a somewhat heavier weight so the requirement for the stick to yank as well as lift, may be subject to elimination.

So, Gentlemen, there are my requirements. Can anybody think of a good way build the "stick" or come up with a Plan C to place a line in a tree for lifting the antenna end that doesn't involve placing my physical countenance in jeopardy?

Tom

I use WWV to check relative receiver performance, depending on time of day you should be able to hear WWV on two or more of its several (2.5, 5, 10, 15 & 20 MHz) frequencies. use a coax switch to flip your antennas between the under-test radio and a good "modern radio" (transciever with an all frequency tuning capability). Compare S-Meter readings.

On Tuesday, June 3, 2014 10:38 AM, "wagstw46@... [TS-520_820_530_830]" <TS-520_820_530_830@yahoogroups.com> wrote:

Hi Dave and Rick:

I have resisted responded due to pretty much always being the odd man out!

Depending on the TS520 owners knowledge and experience there are several questions they should ask:
1. Is there any thing I should look for (correct size fuse, swollen or ruptured filter cap vents, cracked RF Plate choke bypass capacitor etc) or measure before I power the radio? Should I just fire it up or should I soft start it (variac or dim bulb method).
2. Is there any preventive maintenance that I should perform (Ricks question) ? Or spare parts I should buy?
3. How do I know if my receiver and transmitter are performing to design spec? Are there any simple operational tests I can perform to assess the receiver and transmitter performance?

I agree with you regards replacing the HV filter caps even if they ESR and Bridge out OK. Eventually they will fail and they often cause collateral damage. Re-oiling the fan bushing holder felts is good practice as well. I also clean the Aux and Ant TR relay contacts on the older series units and generally replace at least the Aux relay on the TS530/TS830 (now using Kens new design) as cleaning the contacts is not easy or long lived. I also clean all the air variable capacitor rotor shaft wiper contacts, and I lube the VFO gear train with Tri-flow. I also De-0xit the bandswitch contacts and all accessible pots and switches. Of course a good visual inspection and blowing out all the dust including the PA cage. That is about it.

I dont know anything about Ricks knowledge and experience so my comments are more directed toward a newly licensed ham who has purchased a TS520 as perhaps a first HF rig. If you have never owned one you really have absolutely no point of reference as to what constitutes "good" receiver or "good" transmitter performance.

Yes there is something to be said for the If Not Broke Dont Fix It Approach, but "broke" is defined differently by different people. Anytime you go into any of these old treasures to perform preventive maintenance you do so at some risk. Been many a molex connector pulled off a board. Been many a ferrite slug cracked. Easy to break something or induce a latent fault that will come back to bite you later.

With that caveat in mind I offer this specifically to a TS-520 and with direct correlation to all the hybrids:

How do I know if my TS-520 receiver and transmitter is performing at or near factory design specs?

1. All of the owner operator instruction manuals have the receiver and transmitter specs listed near front of the manual. Problem with that few hams have the test gear, knowledge, or experience to measure the listed parameters.

Look into a "fishing bow." Or the adapter gadget to mount a cheap fishing reel (closed-face "spin-casting" sort, the ever-popular, never-fails "Zebco 202" for choice!) onto your favourite bow if you already shoot.

Use "flu-flu" arrows, with the over-size fletchings, and rubber "blunt" tips to keep the arrows from making dents in the moon. Or someone's head. The arrows are more likely to slide off branches and stuff nd fall all the way to where you can get a hand on them.

48950. Good You Tube Loading Video

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-04 14:38:57 UTC
From: wagstw46@...
Topic: 48950 Message: 48950

Member is looking for a good video on how to Load. If someone has a model then share it with us. He referred me to a You Tube video and asked if it was a good one to follow. Unfortunately the answer is no and I have yet to see one that I would strongly recommend.

What was wrong with it?

1. Almost all makers of these videos are confused about what is going on when peaking ALC indication in TUNE mode. None of the meter scales mean anything at this step. You are adjusting the DRIVE CONTROL for a peak in the maximum RF voltage swing and nothing more (both in receive and transmit). Videos go on at length how important it is to keep the ALC indication within the Black Printed Scale and go back and forth multiple times to check to make sure it stays there. Worst part is if the ALC indication goes outside the black printed scale they use the Drive Control to reduce it and put it back into the range! Sometimes they have to turn the Drive Control almost maximum CCW or maximum CW direction to place the meter indicator back inside the box. When they do that they severely de-tune the Ant and Mixer tuned circuits (used in rx mode) and the Mixer and Drive tuned circuits (used in Tx mode) and the receiver sensitivity most notably suffers significantly. The proper way to reduce the level is with the CAR Level pot.

The DRIVE CONTROL is NOT a LEVEL CONTROL!

You are not trying to establish some level of 6146 control grid current. Depending on the rig and the dc operating bias voltage the maximum grid current ranges from approx 35ua to 45ua. 35ua occurs at approx mid-scale of the Black scale and 45ua occurs with meter pegged full scale. That is micro-amperes and not milli-amperes. You are not loading a Class C grid leak bias CW transmitter of olden days!

Where in the manual does it tell you to peak the ALC indication in Tune mode using the Drive control as a level control? It simply says to peak for maximum ALC indication and if it exceeds full scale reduce the Car Level pot and re-peak the Drive control. The question in nearly everyones mind is what full scale? The Black printed range or the entire meter movement range? It doesnt matter. What matters is maximum RF voltage swing and not how many micro-amperes of grid current.

If it makes you feel better then go ahead and peak the ALC indication within the Black Printed Range or Scale and if that peak causes the indication to go outside the far right end of the black printed range then simply reduce it by turning the CAR Level pot ccw. Do not reduce it by de-tuning the Drive control.

2. Common to see the Op when time to dip the plate current (tune the tank to resonance) to flip to Send and then go out to lunch! Yikes!

They move the camera around, they adjust the focus, they adjust the lighting, they ramble on and talk about the step. All the while the 6146 finals are sitting there drawing plate current in a state of off resonance. I am usually screaming at the screen at this point! Truth is pretty hard to have a 6146 tube failure doing this step, but why needlessly stress the final tubes. Do this step relatively quickly. No more than 10 seconds or so should be

required to accomplish the plate current dip.

3. After getting that initial plate current dip in Tune mode some Ops will go to CW Mode and flip to Send and then very slowly advance the Plate Load control until they arrive at 200ma indication and then proudly announce that we are now fully loaded and flip back to stand-by! Sadly they arent kidding!

They never reach over and re-adjust the Plate tune control. So the rig is left again in a state of off resonance. The manual tells you after that initial plate current dip in Tune mode to load the radio in CW mode using the RF relative power position. You alternately adjust the Plate Load and Plate Tune controls for a maximum RF relative power meter indication. There is a reason KW provided the RF meter circuitry and meter position. They understood how to load a Class AB1 linear. The RF meter position is not for some last fine tuning step as some use it for. Use it as it was intended if you dont have an external inline wattmeter.

The Plate Load Control is not a LEVEL Control.

When you open its plates you reduce the capacitance shunted across the dummy load which means you increase the capacitive reactance which means you are shunting more of the tank coil RF circ current thru the external load and less thru the Plate load capacitor. You cannot move it without affecting the Tanks state of resonance. Anytime you adjust it you must adjust the Plate Tune capacitor to restore resonant state. This is especially true as you just come off full meshed state. If you like to use the two capacitors for Dip and Load method have a ball, but not the best way to load a Class AB1 linear amplifier. Maximum rf output power is far more discernable than minimum plate current especially as you load heavier.

4. Last thing I observed in this video is related to operating in SSB mode. The Op then sets the Mic gain pot to No. 8 or 3/4 wide open position and stated that he gets the best audio reports at this position using a MC-50 mic! Never once does he discuss now is the time to use the Black printed ALC range and how to adjust the Mic gain for proper ALC indication on voice peaks. I have never used a mic that required No. 8 mic gain setting. Me thinks those who are giving him good audio reports must not have ever experienced adjacent channel splatter!

I might add I looked this chap up on QRZ and he is an Extra Class holder. I am sure a nice enough fellow and well intentioned.

So unfortunately I have yet to see a decent loading video that I would recommend all new folks use as a model. Most in addition to being wrong on some steps and not best practice make it a needlessly complex and convoluted procedure. Surely there must be someone out there who understands how a Class AB1 grid driven tetrode works and how to load it that has the time and the equipment to make a decent quality video (both production quality and content)? I have neither the time or the video equipment. I am still using 8mm Kodak with no sound! The grand kids still get sunburned off the lite bar!

One last time do not use the Drive Control or the Plate Load Control as Level Controls. They are not.

Hi Jan:

I have gotten quite a few requests for videos on how to load and other things like how to neutralize etc.

Part of reason I have resisted is not only due to how busy I am trying to answer off list emails and get customer rigs off the bench, but I have not taken the time to evaluate what is needed to make a decent video production. What kind of camera, what kind of lighting, tripod, lapel mic, editing software etc. I am sure it is the gambit from $100 to $10,000 and an acceptable job can be done toward the lower end of the scale.

I have some training background from nuclear power training academy and understand video as a training tool, but dont want poor quality video production to detract from the message. We have all seen the dark scenes, glare off the white board, figures too small to read, poor focus, barking dogs and crying babies!

Also hard for me just to show how to load without throwing in some discussion of what is on the end of those knobs and a little how and why and what happens when you dont get the expected results. Maybe need to make a two part one? Right now just how to load would be a big help.

If you get time to make one I would be glad to preview it for you.

Have a great day.

Terry K9TW

A 1 oz. fishing sinker will work much better than a steel nut. The tapered shape tends not to get caught in the branches. The suggestion to use fishing line is quite apropos. It us much slicker and the 1 ounce weight will slide down to the ground.
What worked for me was to use a cheap slingshot that I bought at a local hardware store. It had no trouble getting the weight up over a 70 foot oak.

Terry & the Yahoo group,
I have been involved making video reports for about 25 years at my old research job for the USAF, and I found the best ones had the best scripts. Even if we don't have a final script yet, I think your previous email will make a very good outline for it.
Yeah, most of the homemade video shots look like they used a cell phone camera and held it very unstready.

Jan:

I agree scripted and practiced is the best. If not a script certainly pretty good outline. If you get time look at loading instructions and why recommend a wattmeter on my website www.k9tw.com http://www.k9tw.com.

I am planning on re-writing and tweaking a little. Maybe a separate long and condensed versions. Just not enough hours and as you say those of us who live in midwest need to take advantage of what short summers we have.

Would be outside today but has rained all day. Fortunately no bad storms here yet.

cI am re-posting this as I had inadvertently left off my signature.

I have for sale the above referenced kenwood gear. They all function well. No cw filter just the standard ssb filter. The ts530sp & at230 are a 9 out of 10 and the mc50 is an 8/10. I want $475 for the whole set. Shipping will not be cheap so I am willing to meet within a 100 mile radius of Lindale, Texas, 75771. Email me direct off list or call 903-283-8794.

Alan:

Best one I have ever seen.

There is no reason to reduce ALC indication in TUNE mode to be within the black printed range, but probably best to teach it that way to give them a target range rather than have to convince people it doesnt matter and explain that we dont care about difference between 35ua vs 45ua of grid current. All we want is maximum RF voltage swing at the control grids of the finals. When we have that the ALC bus voltage is at its lowest point and that is what the meter is actually reading.

Also only other thing I would add as a last step is to place meter in Ip position and flip to Send again and check the plate current. For a TS830 should not exceed 265ma although the informal level that most of us use is 225ma. For the TS520/TS820 series should not exceed approx 200ma. The series have different dc input power ratings.

Might then tell or demo what to do if Ip exceeds max (close plates of Load cap and re-adjust tank cap).

Lastly might mention no need for heater warm up, but no reason either not to give them a few seconds rather than place the accelerator to the floor! Also, no reason to check zero signal plate current and set to 60ma each time, but Ok to check as a first step if you want to.

Otherwise it is very well down as all of yours are. I especially enjoy your tutorials and frequently recommend them.

Great.

When new people ask me if there is a good KW hybrid loading video (and they do quite often) I can now refer them to your site.

I also encourage them when they get xtra money to invest in a wattmeter and to use it to load rather than the RF relative power position as it puts a real number to the maximum (approx 100 watts) and it lets them know if there is a problem with their rig and/or their antenna system as the RF meter position will still indicate if you have RF drive or emission issues or are loading into an open and fool you into thinking all is well if you dont have a lot of experience. With inline wattmeter can leave panel meter in IP at that last step.

As I mentioned no operational or technical basis for peaking the ALC in Tune mode in middle of the Black printed scale, but I guess there is a good Human Factor reason. Easy for new people to remember that when loading you peak ALC indication there and when modulating in SSB you talk it up to there.They dont have to understand the what and why. Hopefully if enough interest that will come with time.

I just hate to see people go back after loading to 200ma and try to adjust the ALC indication again as so many videos teach and depending on the model (most notably the TS520) there may be no ALC indication at 200ma.

Thanks for taking time to do this.

That is a good idea. I will do that as soon as I figure out how and get the time. I have a lot of KW hybrid info I could populate it with, but very busy with bench work.

My site is a work in progress and I have struggled to get it where it is as I am not very computer literate. Also trying to do it on the cheap with Google Sites which is free but not most user friendly at least from my perspective.

My rig history (partial) Boatanchor to rice box.
I went from desk filling, made in USA, boat-anchors with huge knobs and slide rule frequency dials... to the (to me) little TS520 that did a big job from a small box a fraction of the size of my Hallicrafters / E.F. Johnson combo !
Next came my Kenwood TS440s with small, dual fucntion, concentric knobs and tiny flush buttons, difficult for my fat fingers to hit and twist properly but I mastered it ! Not I am back to a huge sized radio compared to the TS440s..A Yaesu FT990 that has easy to grip knobs to twist and larger buttons to toggle some funcitons.
It doesn't quite have the sliderule dial like my old SX101a but a large digital freq display that I don't need my reading glasses to see.
Life is good !

John, I found a CW filter for the 520 and it will be here this week . . . so between that and the SCAF filter I should pretty much have things in hand.
I love my K2/100 (loaded) that I built, and I'll probably never sell it because I built it, but the little knobs and buttons aren't that much fun and I really don't like the sound of DSP processing that much. Sort of an old school guy I guess.
One thing you may find amusing, in the original TS-520 QST Review (Sep '74) the author says: "Placement of the various controls proved both convenient and comfortable for operation. While some are very closely spaced on the front panel, no difficulty was experienced in using the system."
I wonder what he would say about today's rigs.

G'day fellow members. I'm new to this group. I have a TS 520 SE that has never been plugged in until now. Last Saturday we put it on a Variac and over 12 hours brought it up to 240 volts. On Sunday a friend that knows more about these radios came over and tuned it up for me and we put it on air for the FIRST time in its life. It's in pristine condition and has that new radio smell to it. I got it from a silent key estate and it will be my baby for a long time to come.

48971. What To Look For?

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-08 01:33:02 UTC
From: wagstw46@...
Topic: 48971 Message: 48971

I was asked what are some of the things I look for when a rig hits my bench and if these things can be done by an inexperienced new owner who may want to make a decision to return a recently purchased KW hybrid or to perform these inspections prior to purchase.

Well it is not very easy to perform anything other than an external visual inspection at hamfests. Looking at pictures on Ebay is not very useful other than it makes me very nervous when I see a photo of a KW hybrid with Heaters on, CAR Level pot advanced, in CW mode, and rig flipped to Send and the seller stating it is refurbed and one of the best he has ever seen! This is not a radio I will be bidding on and paying Ebay auction fever price for.

Ideally it is always best if you can see the radio first hand before purchase. This is possible if you buy at a hamfest or make a local purchase. A local purchase from an owner who can demonstrate the radio is always preferable, but typically the least likely source. You would like to think that if it is in very good cosmetic condition that the insides will not be a disaster and that it will be in good operational trim as well. Of course there are no guarantees.

I think the most important thing you can do for yourself purchasing from any source is to understand your "right of return" and to get it in writing.

I just placed a Visual Inspection Guide under the How To section on my website www.k9tw.com. It details the kinds of things I look for on the rigs that come across my bench. It does not list any preliminary measurements that I would typically make.This is just a list of things to look for that will need addressing as part of normal service and in some cases problems that I pretty routinely encounter. I always record the as-found visual and operational conditions and put that in my final report to the owner.

This check list would not be something that you could very easily use in the field at a hamfest or at a sellers shack. However, should you get the opportunity to look under the hood it would be of use to you or it may be of some use to you when deciding if you are going to keep the radio or return it or perhaps negotiate a better price.

Terry K9TW.

48973. KENWOOD NET UPDATE (June 8, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-08 20:39:13 UTC
From: Mark Gilger
Topic: 48973 Message: 48973

```
Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm
```

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday□s net was run by, Jimmy, WB2KNR. There were 9 stations checking in under good band conditions. We had the following number of radios checking in.

```
3 running TS-520(x)
3 running TS-530(x)
2 running TS-820(x)
1 running TS-830S

The reset were running non hybrid equipment.

Jimmy was running his TS-520.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in under poor band
conditions. We had the following number of radios checking in.

4 unning TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
0 running TS-510

The reset were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).
```

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 80, Sunday☐s total = 85
March 2014, Saturday☐s net total = 82, Sunday☐s total = 73
April 2014, Saturday☐s net total = 64, Sunday☐s total =43
May 2014, Saturday☐s net total = 66, Sunday☐s total = 35
June 2014, Saturday☐s net total = 9, Sunday☐s total = 18 (Month to date)

OK Jeff:

It is not all inclusive list, but gives you some things that you can check visually.

I would add to check the PC board hold down screws. I sometimes find them loose, missing, and once in awhile even stripped threads. OK to back them off and then retighten them but dont go crazy just snug them up. Hard to teach feel! A neighbor once tightened all the bolts on my lawn tractor I loaned him and he handed quite a few broken ones to me when he returned the mower! I think he mumbled something about inferior grade fasteners!

I sometimes find VFO shield cans with missing screws and even find a flat washer from time to time floating around inside the VFO shield can (TS530/TS-830).

I am not a big fan of star lock washers on the PC boards. Why didnt an EE Japanese design engineer at the factory think of that design flaw?

Also, be very careful plugging and un-plugging and cleaning Molex connectors as a routine task. Easy to pull them off the board or even crack the board. I do wiggle all of them with the rig in operation and often encounter an intermittent condition due to bad solder connection or a cracked PC trace at the pin pad interface.

This is not common, but I do find some wire wrap posts that have been unwrapped and a very crude attempt to re-wrap with the old lead wire. You cannot do that as the wire has been work hardened during initial wrapping and is very brittle. You must cut all the old wrapped conductor off and skin back to fresh wire and usually not enough slack to re-wrap even if you have the correct hand wrapping tool. Best to clean the post to remove any oxidation and then just make one wrap and tack solder. I see this mostly on TS-520 series rigs where one or more of the RF "hanging" boards have been replaced. Can be the reason for poor or intermittent receive and transmit functions on the RF board.

Have fun

Terry K9TW

Followng up on my earlier question about alignment step 5 on an TS-530S:

I measured Pin 1 connector 6 (using an RF probe) and found that the voltage is 185 mV. The instructions call for 200 mV +/- 1 dB.

I think that 185 mV is only 0.677 dB from the 200 mV target, so I don't really need to adjust this since the instructions allow for up to 1 dB differential. (Am I correct?) I used the Voltage and Gain calculator on this web page to do the calculation:

Decibels to Voltage Gain and Loss convert calculation conversion amplification amplifier electronics - sengpielaudio Sengpiel Berlin
http://www.sengpielaudio.com/calculator-gainloss.htm

http://www.sengpielaudio.com/calculator-gainloss.htm

Decibels to Voltage Gain and Loss convert calculation co...
http://www.sengpielaudio.com/calculator-gainloss.htm Gain and loss - damping and amplification in dB voltage conversioncalculation amplification amplifier electronics - field parameter - Eberhard Sengpiel sengpie...

View on www.sengpielaudio... http://www.sengpielaudio.com/calculator-gainloss.htm
Preview by Yahoo

But if I do need to adjust TC2 on the VFO board, how would I get to it? The VFO board appears to be completely covered by the Counter Unit.

Thanks in advance for any replies.

Terry,

I just reread your ealier reply and I see that you converted 1 dB to mV in your reply, so I don't need to adjust TC2.

But for future reference, how does someone access the VFO board?

Thanks again,

Louis

Your level is fine. 178 to 224 mv rms is the range. Lots of ways to make the conversion. For +1dB multiply by 1.122 and for -1dB multiply by 0.89.

To align the VFO both high end and low end tracking, CW mode 800hz offset, and rf output voltage you must remove the 4 allen head screws and pull the VFO forward to access the trimmer and inductor holes in the shield can. No problem running the VFO outside the rig to do this. Be careful when you re-insert it as you can pinch the small gauge pilot lamp lead wires as you tighten the screws if they are not in the clear.

Terry -- thanks again for the prompt reply and for all of the help that you've provided.

I've completed alignment steps 1 to 7. I haven't proceeded further because because I don't have a sweep generator (yet). I'm real slow because I read and reread the instructions and the theory of operation while I'm doing this because I'm trying to understand what's really happening behind the scenes. (Thanks for your patience.)

A few observations:

-- LSB used to sound (on receive) just slightly bassey and muddy. Now LSB sounds just as clear as USB. Actually, the rig now sounds just like those flashy new rigs!

-- Sensitivity seems to be improved on all bands, although I can't really confirm that because I don't have a sweep generator (yet) and because band conditions are always changing. But I can confidently say that WWV is definitely stronger.

-- The VFO used to slowly drift downward about 100 Hz every 5 minutes for the first 15 minutes of operation, then drift up and down about 100 Hz every so often after the rig was fully warmed up. Now the VFO is almost rock-steady within about 3 minutes after the rig is powered on.

Some of the alignment instructions call for an AF VTVM. Can I use a Fluke 179 as the "AF VTVM"? It is a true RMS DVM.

Hello!

My name is Bret McHone, KK4YIC, and I am the proud owner of a Kenwood TS-520. This radio was definitely a learning experience as I grew up in the age of digital equipment and had never been around vacuum tubes, radios, or anything really other than modern PCs. I can build an intercontinental network infrastructure, but holy crap these old radios make me feel green behind the ears!

With that said my first radio has been a bit of an odyssey. After a local ham checked it over as much as he could I bought the radio from him for $125. On his Bird 43 watt meter it was showing putting out about 110 Watts on 20 meters into a dummy load and the receive was great! After going over a few things with him and testing it out on my antenna it looked like I was in business. I spend a couple days poking around and had a couple short QSOs (my first ones ever, in fact).Well, due to operator error/stupidity I ended up not giving the tubes enough rest during one the tune-up processes and popped my cathode resistors. Having never worked on electronics before I grabbed a soldering station that the ham I bought the radio from had given me and practiced on some old computer power supply boards. After figuring out which resistors were the problem I shakily replaced them, though successfully without damaging any of the other components!

At the time I didn't have a good SWR/Power meter so I grabbed an antenna tuner that had the meter built into it. When set as either direct or tuned on the tuner I kept getting really low readings for my power even though the SWR was still showing fine. When trying to figure out what was wrong I didn't pay enough attention to what I was doing and made the *SAME* damn mistake again. POP goes the resistors...

I ended up spending another week stewing over my own incompetence and trying to determine what I had done wrong and where I was messing up The same ham the sold me the radio extended even more help and actually picked my tubes up and took them to be tested, During that time I replaced the cathode resistors (again) and the screen resistors since they were measuring around 138+ ohms instead of 100 ohms and I had the parts on hand (thanks to K4EAA for having those easily purchased and available).

I borrowed a Drake W-4 watt meter and dummy load to test out the radio after replacing the parts. I then started following the tune-up procedure to the letter provided by K4EAA and I have to say it was night and day. I let the radio warm up for about 5 minutes and began tuning little by little giving at least about 5-10 seconds between the short transmits needed to dip the plate and adjust the load. I was a bit gun shy at this point and didn't want to risk blowing something else up on the radio so I kept on tuning to get my IP up to about 225ma in transmit and VOILA! After taking my time and following the advice of veteran hybrid users I had a radio that was putting out about 115 watts according to the Drake W4! Now, I'm more than happy with 100 watts so I don't plan on pushing the radio, but I was just looking for that 225mA area recommended by K4EAA. I hooked the radio back up to the tuner in direct mode and tuned up again and guess what? LOW POWER READINGS! I put the W4 in line between the radio and the tuner and the drake showed normal power! So it was my @#$% meter on the tuner that isn't calibrated correctly!!! All that fiddling and trouble mostly

because of a faulty readout!

Now that I"m on the air I am one happy camper and I hope to try and get on the net with y'all this weekend if at all possible. I'm a newbie that generally has to learn the hard way, but I love to learn and I *LOVE* that you can actually work on these radios instead of having to send them back to the factory to have a board replaced and shipped back to you.

I will be slowly increasing my collection of tools (and understanding of the tools) in order to work on this thing and keep it running. Heck, learning how to fix it has been just as much fun as talking on the air! My next job on this radio is to attack the marker board because the calibration tone isn't being generated, but that's for another day!

73 to all!
Bret, KK4YIC

I know there is a "QRP mod" I've been looking at for the 520 where you apply a small negative voltage to one of the pins of the VFO port. It's supposed to allow you to drop the output power while still loading it up normally so your sound quality doesn't suffer. Perhaps it is something similar for the 830?

Good luck!
Bret, KK4YIC

Louis

I dont recommend alignment on a routine basis or as a substitution for troubleshooting. Once aligned radio should stay in that trim for many years. However, I do perform a 100% complete factory service manual alignment on all KW hybrids that come across my bench as a way to re-base line the radio. I do that as there is no way to know how many owners it has passed thru and how many golden screw drivers have been applied. In addition to improving on performance I can usually find some operational issues during alignment.

So I understand why you might want to align your radio. It also helps you learn how it works and to locate and identify test points, adjustment devices, and acceptance criteria. It also teaches you real quick where the schematic and service manual errors are at and unfortunately they abound. You will get a real lesson on a TS820 when wrong test point, wrong trimmer, and wrong acceptance criteria is called out!

Just remember any time you go in to alignment it is easy to damage things and add needless wear to the adjustment devices. Besides breaking things you can induce latent failures which can manifests themselves at later date with intermittents. So it should not be a spring tune up procedure like rotating finals or lubing the fan bushings.

I dont know the specs of your Fluke DMM. Easy to look them up and see what the AC frequency response is. Most DMMs AC frequency response is lower than that of a VTVM. I have a nice BK 40,000 count true RMS DMM and it is only good to 1000hz. My Heath VTVM is pretty accurate up to 20khz and will measure higher than that.

Also I dont use any DMM to align the KW Hybrids other that to measure and adjust 9vdc regulated and the RF-1 level. I only use Analog meters (VTVM, True RMS AF VTVM, and RF Millivolt meters). Most straight VTVMs can be used on AC range to do what you need. If you dont have a VTVM then of course use your Fluke or whatever DMM you have. Suggest you verify what its input impedance is on all ranges and if you cant find that out just try measuring the AGC bus and see what happens to your receiver and S meter. It will tell you if you should be using that DMM for KW hybrid work.

Lastly you dont need a Sweep Generator to check your receiver sensitivity? Not sure why you think that is instrument needed? I good calibrated RF signal generator with a good step attenuator is all you need to actually measure sensitivity. Absent that you can do AB testing with another unmolested commercial ham band rig.

It is easy to measure MDS and AGC threshold if you have a RF sig gen. For quick check just start by injecting -73dBm or 50uv on each band and note the S meter reading you will have a good idea about how the receiver is hearing. Should see approx S9 with that level into the SO-239. Then step the output down to -113dBm or 0.50uv and you should clearly hear signal on all bands (with no S meter indication) and most hybrids can hear even lower to at least -119dBm or 0.25uv.

Only thing you need a Sweep Gen for with a TS530 is to perform PLL BPF alignments. Fortunately in my experience people seldom mess with these coils. PLL board is seldom

messed with unless CB hacked. You can do a rough check just by injecting VFO signal frequency range into Q39 and then measure the RF voltage level at output of Q35 emitter. Should see peaks per the center frequency response curves in VCO alignment steps. Can do it just using the VFO but not as accurate due to the VFO gear reduction making the peak very broad. Much better to unplug the VFO input at PLL board and inject from 5mz to 6mhz at approx 200mv level from RF sig gen and watch the RF voltage peak at Q35 emitter as you slowly swing the VFO and rock it back and forth to get peak RF voltage indication. Not as good as Sweep Gen method but will tell you if grossly off and needs alignment. Has to be pretty bad for the digital display to blank at either end of the VFO range.

Terry,

Thanks for the very helpful reply.

As a bit of background, I'm the original owner of my TS-530S and the alignment check that I'm doing now is the first one that has been done in its 32 year history. I'm a strong subscriber to the rule of "If it's not broken, don't fix it". That said, now that I have some of the right equipment to check the alignment -- and since 32 years and thousands of operating hours have passed, I figured that I'd at least check what I could. I did find that a few voltages were slightly out of spec so I adjusted them, so I figure that this exercise has been worth it.

My Fluke DMM is good up to 100 Khz.

Yes, this is largely a learning exercise. I'm real careful and I figure that the potential reward outweighs the risk. I'm not touching any slugs that don't truly need touching -- but thanks for the warning!

Louis
W3LMW

P.S. A local ham / semi-retired RF engineer was kind enough to do a NIST-traceable calibration for me on my Tek 2445 scope. Fluke checked my DVM calibration at no charge. I calibrated my frequency counter by using my calibrated HP 3586A. I don't have an RF signal generator yet -- watching for the right deal on an HP 3325A, since it will do just about everything that I need, including being an RF signal generator and sweep.

He's in the tune mode, not LSB/USB; In the "tune" mode, you need to get some ALC showing first, then some Ip will be showing.
And the "load" dial is fully CCW....place it in the middle, is a good place to start with.

Jan,

The LOAD control is set fully CCW during initial transmitter tuning in TUNE mode, not in the middle of its travel as you have indicated.

IP current flows in the final tubes regardless of the Mode switch setting and whether RF is present at the final tube grids or not. TUNE mode reduces final tube screen voltage to lower the final amplifier's input power level but it does not reduce the final amplifier's idling current to zero.

"Between 50 and 60ma plate idle on all bands"?

That sounds to me like unstable final amplifier IP idling current, possibly due to a dirty/corroded bias pot, corroded final tube sockets, or bad final tubes (heavy gassy final tubes). There could be other issues causing instability in the final amplifier's IP idling current. The USB and LSB IP idling current should be a stable 60ma in USB or LSB on ALL bands.

Let me me rephrase that Mike. I was not in front of my rig when I posted. All band plate idle is 51ma. I knew it was between 50 and 60ma. I even posted earlier that 40m was at 60ma. That's wrong it's at 51ma.

I'm thinking it may be the drive tube. If I turn CAR all the way up. The drive doesn't peg on any band. I can now confirm that there is no drive shown on 10m also.

Duff:

OK whenever you have very low or missing drive on just one band it is often due to bad/dirty bandswitch contacts not switching in that bands Mixer and/or Drive coils in the Driver grid and plate circuit.

As the Driver tube ages low RF drive is typically manifested on 10 meters first and not 80 meters and first simple thing to do is to replace the Driver tube. Not typical that the Driver tube would be the cause of no RF drive on just 80 meters.

These problems are relatively easy to find and fix if you have a VTVM and RF probe.

You can run the TX Level diagram in the Service Manual to see where you are losing RF drive at on 80 meters. Not typical to lose the TIF signal as it is not band dependent. I would look at the output of the TX Mixer at MD. You should have approx 1.5v to 2.0v rms at MD. If it is low or missing then I would measure the VCO input level.

Since the 820 is a PLL based radio you could be missing the VCO signal on just 80 meters. The VCO signal provides the Local Oscillator (LO) signal for the TX Mixer. Again need a VTVM and RF Probe to measure VCO level at the TP on the RF board. Should be approx 1.0 volts. The 820 PLL still uses Het Osc crystals and the soldering can be bad at the leads. The xtals are on the PD board.

Absent basic test gear this can be difficult to troubleshoot.

Hi Mike:

No disrespect to Jan but you are correct.

The Load control has nothing to do with ALC indication. As you note it is purely a function of sufficient RF drive voltage swing to overcome the dc offset set by the operating bias voltage level.

Almost all cases of no or low ALC indication are due to the RF voltage swing not being sufficient. Must be greater than approx 40rms rf volts for bias voltage of approx -55vdc.

I also never teach new people to start loading with the Plate Load control capacitor un-meshed. At 50% open it can make that initial plate current dip for tank resonance to be almost imperceptible to them. This serves to confuse them. When they get some experience they can start with heavy RF current transfer to the load right out of the shoot.

Suggest that all new members watch Alan W2AEW new video on loading a KW hybrid. He demonstrates how to load just as the instructions in all of the owners manuals direct them to do. Use the RF relative power position or an external watt meter and load for max RF output without exceeding max IP. Cant get any simpler.

That is a very good point, Terry. After reviewing "Table 2 Initial Switch Settings for Transmission" (820 Owner's Manual), I didn't see any mention about presetting the Load control. I just experimented with the load control at full CCW and in the 50% range, and yes, the Ip dip is more pronounced. Awesome, thanks for the tip, I never realized that before this time. I stand corrected.

Mike,
Well, I do agree with you. I noticed in the Tune mode, with the CAR control set mostly CCW (a low CAR setting), there isn't any indication of Ip on my 820's meter. In CW/USB/LSB mode, we agree that we can see the 60ma of Ip even with a low CAR setting, yes.

No problem Jan.

Sometime I would like to make a video on how the Pi-network works. Would have to include a little primer on parallel resonance and how tank circuit converts DC to RF.

I find it really helps to redraw it out of the Pi config and draw it as a conventional parallel resonant circuit with the tank cap in one leg and the tank coil and loading cap in series in the other leg. Can then place the 50 ohm dummy load resistor across the plate load cap and can see that you have 2 parallel paths for the RF circ current in the tank. With dummy load connected you have a resistor in parallel with capacitive reactance and with a real antenna connected have a complex impedance in parallel with the plate load cap. Depending on the antenna can have inductive or capacitive component. Easiest to just think of it as 2 parallel resistors and remember how current divides between them.

With the Plate Load capacitor plates fully meshed (full CCW) you have maximum capacitance and we know that capacitive reactance is inversely related to capacitance (1/2Pi x F x C). High capacitance means low Xc which means that the approx 2.8 rf amps of circ current is flowing thru this low reactance of the plate load cap and not thru the dummy load or antenna. When you open the plates you lower the capacitance which then raises the Xc so RF circ current in the Tank starts to flow heavier in the dummy load resistor and less in the plate load cap. It is actually very simple ohms law for parallel resistors. When fully loaded to approx 100 watts out you will have close to 1.4 rf amps flowing in the Plate load cap and approx 1.4 rf amps flowing thru the 50 ohm dummy load.

Anytime you move Plate load cap then you have to touch up Plate Tuning (tank) cap to restore the tank to resonance.

This behavior explains why it is a good reason not to load these parallel 6146 grid driven tetrode Class AB-1 linear amplifiers using the old dip and load method. The more you open the plates of the Plate load cap the heavier you load and the less and less discernable the plate current dip becomes. This is not the case with RF voltage that the RF position of the panel meter reads or RF watts on an external wattmeter. Always able to see a very obvious and well defined peak in RF relative power or real power on your wattmeter.

That is why all the KW manuals describe using the RF meter position to Load these radios and why they provided it. Some people somehow think of using the RF meter position only as some kind of final "fine tuning" step after dipping and loading and I dont know where they find that usage described in their manual?

Anyway I dont load with the plates fully meshed anymore either as I have been doing this for a very long time and can pretty quickly load on the fly, but with new folks it is good idea to start by having plates fully meshed so they can very clearly see that initial tuning of the Tank to resonance.

Have a great day.

Terry K9TW

I am currently looking to possibly purchase the mfj apartment/balcony antenna for my home hf station due to me living in a townhome currently and not able to put up much of an antenna there. I know from reading about it that it has a coil that can be adjusted to allow it to be operated on the different bands it supports. My question is with the adjustment being made on the antenna would I need a tuner for the antenna for me to use it with my TS-520? This is the link to the product description of the antenna I am referring to:

MFJ Enterprises Inc. http://www.mfjenterprises.com/Product.php?productid=MFJ-1622

MFJ Enterprises Inc. http://www.mfjenterprises.com/Product.php?productid=MFJ-1622 The MFJ-1622 Apartment Antenna covers 40 through 2 Meters, mounts outdoor to windows, balconies, railings, and works great indoors mounted to desks, tables, and bookshelves!

Chris,

If you follow the instructions that are included with the antenna, cut and attach the make the tap according to the instructions for each band, and cut and attach the radial wires according to the instructions, the antenna will work without a tuner. However, you must understand that the antenna is not for permanent use, a high level of RF will be present which can cause problems with transmissions. I have a similar antenna I purchased when I lived in an apartment in Germany, working for General Dynamics Network System at HQ EUCOM, Vaihingen, Germany. The antenna was mounted on the window sill about a foot from the stations with only one radial on 20 meters, not a good location for the antenna. The radial ran around the base board of the bedroom. Needless to say there was plenty of RF in the shack. I ended up replacing the antenna with a 3 element yagi that hung from the attic rafters (many German house attics are huge, long and tall enough to walk around upright with 4 feet to spare above my head), I lived on the top floor and had access to the attic. The building I worked in on base had an attic that ran the entire length of the building, at least 100 feet long or more. One could run a half wave horizontal 40 meter dipole without bending the end and still have over 50 feet to spare. I wish my attic was that big!!

This is not really a great antenna. A friend of mine with similar issues as you is going to put a automatic antenna on his vehicle. He is going to run a cable from his home and put an electrical box outside with a coax connector in it. He is going to make up a jumper cable from the truck to the box and they sure can't say he put an antenna up on the property. Just don't forget to disconnect in the AM before you have had your coffee!! Brad KB2CHY

MFJ apartment antenna , Need a tuner ? No ! you need a decent SWR meter to set the tap on that coil and a good counterpoise wire run , no additional tuner.

Well if the manufacturers info is to be believed, you won't need an antenna tuner.
However you will most definitely need an SWR meter to set up the antenna for the band and frequency of interest. You would do that with your transceiver on low power and adjust the taps on the antenna for minimum reflected power.

The hybrid Kenwood radios do not require a tuner as long as the antenna you are using are within 3:1 SWR, the beauty of these radios is that you can use the
radio to tune it to the antenna you are using.
I use home made Off Center Dipole wire antennas that don't need a tuner no matter what radio you use and get great results!

Hi Chris,

Mike and the others make very good points. Is there any way you can put up a dipole even if indoors, or perhaps a shortened loaded dipole on the balcony --like two Hamsticks? I have had several experiences with my condo and HOA restricted antennas. In one case I put out a sloper for 20 meters from the balcony to the ground, and put it out at night, taking it in after operating and before dawn. That worked pretty well. I also have a Buddistick shortened loaded vertical. That requires a counterpoise as does the MFJ antenna, and it gives me plenty of Rf in the shack. I could tell by the zapping on my fingers on the CW key. The Rf made the CW keyer give odd dots and dashes. I was able to cure the Rf problems by inserting an Rf choke (from MFJ) into the transmission line.

The MFJ apartment/condo antenna is one option, but explore others and don’t give up-get on the air with your 520 and have fun trying different antennas.

Chris and others,

The MFJ-1622 and MFJ-1624 are basically the same antenna. Chris said he has the MFJ-1622.

The MFJ-1622 is the apartment dwellers window mount antenna.
The MFJ-1624 is the mobile antenna.

Both use the same manual tapping coil and same whip antenna.
Both have the similar power ratings.

The MFJ-1622 comes with everything, including 50 feet of coax cable with PL-259 on one end of the coax and eyelets on the other end of the coax plus 35 feet of counterpoise wire.

The MFJ-1624 requires additional accessories such as coax cable, counterpoise wire, and a mount.

Both will require an SWR meter for proper tuning of the antenna.
The antennas must be tuned, manually, when switching bands. This means the tap on the loading coil must be moved to a different tap and the counterpoise will have to be cut to proper length.

Proper safety precautions must be followed to prevent accidental RF burns!!

Both antennas will result in a large amount of RF in the shack if the antenna is mounted in close proximity to the operating position.

The antennas will work. I have a German version, exactly the same as the MFJ-1622, and I worked the states from Leonberg, Germany, 12km from Stuttgart (I was DA1TNJ) with 80 watts on 20 CW. As I said earlier, the antenna was mounted on a window sill about 2 feet from the operating position.

Chris, if you want more information, the following links will allow you to download the manuals for both antennas

MFJ-1622
http://www.mfjenterprises.com/support.php?productid=MFJ-1622

MFJ-1624
http://www.mfjenterprises.com/support.php?productid=MFJ-1624

Each page has a link that will allow you to down load the manual for each antenna.

Members

I do not know if this topic has been covered here or not and if it has I apologize for covering old ground.

I have several KW hybrids that I have repaired and aligned and I leave the covers off and use them primarily to take measurements to assist me in troubleshooting. Among other things I have installed the black Nichicon Type GN 900vdc anode supply HV filter caps in these radios. These are the ones that the top of the can is bare metal that instead of having rupture diaphragms on the bottom between the terminals they have an X shaped relief cut in the bare exposed aluminum top.

Today I had a TS-520S on the bench and the Yellow speaker wire cable was in my way so I coiled it up and was tucking it in the space between the VFO and the AVR board and on top of the 2 HV filter caps when there was a very loud bang that scared the heck out of me. When I recovered I could see a burned mark on the aluminum can top. Fortunately I did not get shocked and no real damage done.

I grabbed my DMM and measured from top of the can to chassis ground and read 450vdc! Only the first cap in the 2 series string has potential on the exposed aluminum.

The original tall factory Black Marcom units have no exposed metal and the Blue vinyl case replacement caps have a fiber disc cover on the top and no can metal is exposed. I have the Blue style replacement caps in both of my TS-830 operating rigs. I believe that Ken K4EAA formerly sold these. I have been installing the Black GN units that I have bought from Ken K4EAA and from Newark and other suppliers in all my customers radios for quite some time now and they all have the top of the can exposed. I never gave it any thought.

So the lesson is that we now have a rattlesnake on the top side of the radio that is not inside the metal shield of the PA cage. If you were to touch the chassis with one hand and make contact with the bare top of this HV filter cap you would be in for a very nasty surprise.

I am thinking about making or buying a slip on plastic or vinyl cap for this 1st capacitor in the doubler filter to protect future customers. I am going to take a look at Lowes to see what they might have that would just slip over the capacitor.

Again if this is well known I must have been sleeping. This was a surprise that I didnt need to experience today.

Not sure it qualifies as a near miss event, but as close as I like to get. I dont want anyone to get shocked or worse.

Happy Fathers Day to All

Terry K9TW

Ouch! I'm glad you escaped, Terry. Whew!

Just last week I installed red 3/4-inch round vinyl stick-ons on the top of my hybrids' HV caps both for warning and self-protection purposes. I obtained them at a local craft store (Michael's, in this case). I had read about the danger somewhere in this forum's archives, I believe.

I just did a little search on eBay and found the same "sticky" things from a vendor advertising "vinyl polka dots", or some such.

73,

Craig

They're about the same size as the vinyl "pipe caps" you get for the end of certain sizes of heliax, aren't they? I must have a rummage in the junkbox at work...

Terry,
What a coincidence. I actually learned of this about a year ago when I visited a seller of a TS830 here in Dayton. He runs a hobby business on Ebay and buys, fix-up, then resells Ham equipment. He had replaced the two 450V caps and he was point his finger to the newly installed caps (while the 830 was switched on), when he got zapped from that exposed aluminum top surface! From right then on, we both got educated about the hazard.
I have placed 1" wide electrical tape over the cap's top surface (and trim the excess w/exacto knife) from now on. But, even with the insulating tape installed, I'm still cautious, and I always remember that day in his basement shop.
Jan N8CBX (I own that 830 now)

You could try 'aluminum tubing end caps' to check sizes/costs/availability.
I know that (DXE) DX Engineering has a selection of them.

49021. Hybrid Net Update (June 15, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-15 19:35:06 UTC
From: Mark Gilger
Topic: 49021 Message: 49021

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday□s net was run by me, WB0IQK. There were 19 stations checking in under good band conditions. We had the following number of radios checking in.

6 running TS-520(x)
3 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
1 running 599 twins

The reset were running non hybrid equipment.

I was running my TS-830s into an Drake L4B amplifier

The Sunday net was run by me, WB0IQK. There were 16 stations checking in under poor band conditions. We had the following number of radios checking in.

2 unning TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-510

The reset were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 80, Sunday☐s total = 85
March 2014, Saturday☐s net total = 82, Sunday☐s total = 73
April 2014, Saturday☐s net total = 64, Sunday☐s total =43
May 2014, Saturday☐s net total = 66, Sunday☐s total = 35
June 2014, Saturday☐s net total = 28, Sunday☐s total = 44 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

If you want a nice neat professional looking and permanent fix I agree that vinyl end caps for aluminum tubing would be a good way to go. Very easy to just slip on.

The cap OD is 35 mm or 1 3/8 inch.

DX Engineering sells a black vinyl cap in that ID that is 1 inch long. They sell them 8 for $8.95 plus shipping.

I didnt get chance to go to Lowes or Home Depot today. I plan to do so tomorrow to see what they have.

I think we need to have a cover that wont prevent proper pressure relief vent operation.

Terry K9TW

Rob:

Only first one in the string is hot, but you are correct best to treat both as hot. Of course should never be a reason to bare hand touch them, but they should be protected from inadvertent touching.

If you look at Nichicon App notes they talk about not relying on the case for protection and to contact the engineering department if need insulated cases.

Couple of Fundamentals Of Electrical Safety include:
1. Nothing is Dead and unless verified de-energized and grounded.
2. Never go within reaching or falling distance of energized equipment.

That is why we have talked so much about how to safely deal with the top of the RF Plate choke inside the PA cage.

Easy to point at something with no intention of touching and mis-judge how close you are.

When it happened my first inclination was that the cap was defective and as I thought more about it realized it was not. I should have known better.

I've used black electrical tape cover the exposed end of the cap. Worked well for 30 years. I don't need to get fancy with insulated end caps. If you take your time, you can make the tape installation even look neat.

I would add #3 to that list. Never use two hands in any unit that may have high voltage. One hand should always be in your pocket.

Add one more that I follow: When in doubt ground it out!!

This, of course doesn't just apply to the 820 series.
There are many transmitters that use series connected electrolytics to
get a high voltage high value smoothing capacitor. The record I have
seen was 5 or 6 in a 1KW linear!!
They MUST always be treated with respect until one KNOWS that the case
is grounded, or at least well insulated.

Vic,

Yes..or lacking proper 9 pin jumper plug...you can use a stiff piece of wire to connect holes for pins 8 & 9 together on rear socket. Without this...the rig won't work.

Consult Pg 10, Fig 4 of the TS-520 Operators manual, or Pg 8 of the TS-520S Operators manual

Yes. Details are in the manual, but without it the VFO has no power supply and you won't get far like that.

Yes tape is certainly an option, but I am not a tape or glue kind of guy when it comes to my radios.

Everyone has different definitions of quality and how they spend their discretionary income.

Also, as I mentioned probably not a good idea to impede the pressure relief venting which tape could certainly do.

The one hand in pocket thing is mentioned a lot and sounds good, but in my opinion not very practical. You often are using the other hand to hold flashlite, use a tuning tool, change meter range etc. Plus could affect your balance.

Yes nothing is Dead unless verified de-energized with a known good contact voltage meter and then grounded. It is the only safe way to bare hand touch anything, but the practice is seldom religiously observed. A contact meter should be used and not a proximity device. It is called a "live-dead-live" test.

De-energized just means you turned off the switch or breaker and maybe placed a Red tag or Lock on it. Dead means you de-energized it and then tested to verify you opened the correct switch before applying the safety ground. That means literally affixing the ground and not just tapping it on the point.

Terry,

Thanks for the informaiton. I just replaced the caps in my 530. I will take a look.

I had a mfj 12 v switching power supply to go bad. While the unit was on, I was inspecting and touched the top of one of the electrolytic caps. The shock was so bad my arm shook back and forth.

Learned never to do that again!

I can actually answer this one because it bit me just a week or so ago.

I purchased a TS-520 from a guy at a hamfest, lugged it to the car (that thing is heavy and his trunk was as far from my trunk as it could have been and still been in the same county:-), got it home, fired it up...and... nuthin'! I could tell that major parts of the rig were operational but no signals could be heard.

Just about the time that I was feeling that the seller "had seen me coming" someone on this very group mentioned that when a remote VFO is not used, a dummy plug has to be in place to supply +V to a number of circuits, the internal VFO being the most obvious.

Looking at the schematic, I quickly determined that pins 8 and 9 (If memory serves me) need to be shorted together for the internal VFO to receive power. I confirmed this fact with a clip lead and then, since I didn't have a plug that fit (It was a 9 pin tube socket for crying out loud...who does that?) I soldered a jumper in and voila! the rig works as advertized. Apparently, the previous owner left the plug on the desk at home.

Confirm the pin numbers before you go in with a soldering iron, but I'm sure the missing plug is the problem.

Hey, I have used busted-off octal tube bases and (un-busted) tube
sockets for all sorts of things. They're perfect for a lot of uses,
cheap when you can scavenge the parts, and have that nifty "It WORKS!"
quality as well.

> I soldered a jumper in and voila! the rig works as

I am not exactly into modifying things, but this is one thing I am going
to do. I am going to bore a small mounting hole in the backplane close
to this plug and mount a switch there for a permanent jumper. Next time
I'm in St. Louis at the Gateway supply store (my electronics CRACK
shop!) I will be picking up a small bat-handle or similar with a control
lock cover of some sort on it.

here will be a label produced for the two positions, as well. "External
VFO Installed" and "Internal VFO ONLY" to be clear what the switch is
for. It will be locked in "INTERNAL ONLY" mode since I don't have an
external VFO that will do for a 520SE. Not that I know f anyway.

Hmmmmm.... I have the external VFO / SSB adapter box for that old
lead-weighted boar-anchor Heathkit Apache radio..... Nah, it won't be
anywhere near close I'm sure.)

If I may make a suggestion. I would think twice about soldering a jumper onto the Remote VFO 9 pin socket between pins 8 and 9. If you solder a jumper between pins 8 and 9 then you will not be able to use any remote VFO (VFO-520 or VFO-820) with your 520 without removing the soldered jumper between pins 8 and 9.

By the way, the VFO-520 and VFO-820 are the same VFOs and are interchangeable between the 520 and 820. That means a VFO-520 can be used with a 520 AND 820. The same goes for the VFO-820, it can be used with a 820 AND a 520, both without any changes what so ever in the cable and/or the 2 VFOs.

I mean no disrespect but this is another example of where operators/owners did not take the time to read the operator's manual BEFORE attempting to operate their newly acquired KW hybrid. If the operator's manual was not included in the sale then download it, it's free, and read it first! A lot of operator error problems can be prevented if operator's would simply read the manual first. If you have problems understanding what the manual is telling you, come and ask for help but don't ignore reading the manual FIRST before you operator you newly acquired KW hybrid!

7 and 9 pin plugs can be made from a 7 or 9 pin socket and some brass wire from a hobby shop.

I date back to the days when ALL radios glowed in the dark. There have been *many* times when I have used octal tube sockets and bases for connectors. Two of the old FT-243 (?) crystals would also fit into an octal tube socket so they were great for that, too.

The problem here is that you can't break the bottom off of a 9 pin tube and (well, not easily, that is) add a jumper and shove it into a 9 pin tube socket. That's kinda hard on the fingers:-)

I took that into consideration, when and if (I doubt I will EVER do it)
plug an external VFO into my 520, I'll just snip out the jumper.

Terry,

Thank you for an important heads up . I never would have thought the top of the caps would be hot. But now I know.

At age 16 I had a nasty encounter with the finals of a Swan 350. A lesson that has allowed me to reach 59 without a repeat. High voltage demands respect. Glad you were not injured. Your post doctoral fellowship lectures on the care and feeding of Kenwood hybrids would be missed. Respect the HV.

Not so. Cardinal rule when repairing TV sets with HV. Same difference Terry. Have a lamp mounted so you don't need a flashlight. The reason for the hand in the pocket is to save you life. No complete circuit through the heart, thus the reason for one hand to be in your pocket. Have done it for many years and the very first thing I was taught in TV class. That was in 1964 my friend. Very practical advice to you. Brad KB2CHY

Subject: RE: [TS-520_820_530_830] HAZARD AWARENESS

The one hand in pocket thing is mentioned a lot and sounds good, but in my opinion not very practical. You often are using the other hand to hold flashlite, use a tuning tool, change meter range etc. Plus could affect your balance.

Yes nothing is Dead unless verified de-energized with a known good contact voltage meter and then grounded. It is the only safe way to bare hand touch anything, but the practice is seldom religiously observed. A contact meter should be used and not a proximity device. It is called a "live-dead-live" test.

De-energized just means you turned off the switch or breaker and maybe placed a Red tag or Lock on it. Dead means you de-energized it and then tested to verify you opened the correct switch before applying the safety ground. That means literally affixing the ground and not just tapping it on the point.

Probably worth mentioning that when replacing these caps, one should inspect the mounting clamps for any sharp edges or burrs that might inadvertently cut through the cap coverings as this could short the aluminum cap casing to ground when tightening the clamps.

Or you can take a defunct tube, stick the pins through a disc cut to the pin circle diameter, made from a piece of thick-ish hard/stiff plastic. Get the pin circle in the plastic disc exactly the right size, shape, and spacking by heating the base of the dead tube (and the pins mainly) with a hot-air heat-gun, then just press them into the plastic until they are all the way through the disc.

Pop the tube with the plastic disc now stuck on the bottom into a paper or plastic bag and proceed to gently beat the crap out of the glass part. Then snip the wires off the tube pins once you can get to it with the diagonal cutters.

Remove the last of the glass from the plastic disc, solder wires on the pins where they used to be connected to the tube elements being careful not to get things so hot the plastic disc sags and loses cohesion with the pins. Some fast-set epoxy applied first will help with this little problem.

The whole thing can be made using a pharmacy pill bottle, the amber sort, cut down a bit so you can reach the pins for soldering. This gives you a cylindrical cover by which you can grip the thing to plug it into the socket. Sockets can be mounted inside the same sort of pill bottle. If you use the larger size, you can use small nut/bolt sets on the ears of the socket mount to hold it to the bottom of the bottle. Then use a small hole saw bit, an appropriately-sized spade or Forstner bit, or a Dremel tool to cut out the pin circle from the bottom of the bottle, leaving the outside ring where the nut/bolt sets are.

Sounds like more work than it really is, it always comes out the right size and spacing, and you get rid of a dead tube at the same time. I can make a matching set in about ten minutes using two pill bottles, the heat gun, an old tube and socket, and a couple of drill bits.

Don't cut yourself when smashing the tube, or when fishing out the bits you want to re-use from amonst the busted bits of glass and tube elements. And DON'T breath in the dust from the tube elements once it is broken. Several sorts of odd metals in there, and "heavy metal poisoning" is not funny. (Nor is it getting sick to the stomach at the crap that is being passed off as music lately, either.)

I am glad that Terry brought this hazard to everyone’s attention. I have those Nichicon aluminum caps installed in my 530S and accidentally touched the aluminum top of the first one in series and got a real scare. Measurement with my DVM from the top of the cap to ground gave something like 375 volts! Since then I have cut a piece of yellow self-adhesive insulating tape into a round circle that just covers the aluminum surface.

49052. 5203se not tuning up when in TUNE or CW modes

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-17 14:24:06 UTC
From: jon_g4fut@...
Topic: 49052 Message: 49052

I have several Kenwood hybrids and lately my 520se which has been working well can now only transmit miliwats. I have checked this in CW on an adjacent RX when I plugged in the morse key. I have replaced the 3 tubes and they display the usual 60ma bias OK. but no RF output HT is 900V, and the calibrator give a S2 only signal on the meter. This problem started when I removed the CW filter as it was duff and wanted to replace it with a known good one. All switches , e.g. SG on the rear are as they should be, although I had to replace the 2A 12V fuse as it had blown. I can get no reading when in TUNE and the other RX shows no received signal. I have the service manual and have done the usual "trouble-shooting".

Grid Voltage Test
With SG switch OFF the DC voltage pin 5 of PA tube socket is 100 V on receive and 80 volts on transmit when in CW mode.
In SSB mode the voltages are;- 100 on receive and 85 on transmit.

PS. I use a 'scope to tune up the TX as well as a dummy load.

Any ideas would be most welcome.
Regards
Jon G4FUT

Basic on what you have said, it sounds to me like you created a short in the 14VDC supply that flows through the MODE switch S3-8 and the Narrow/Wide switch S10 and is present on the IF Unit "SSB/CW" terminals. A short such as this will cause the 2 amp fuse to blow. If the 2 amp fuse blows then there will be loss of 14VDC from the Rectifier Unit (relays will not energize with either the SEND or PTT switches) which result in loss of +9VDC and +3.3VDC which supplies the LV for the solid state circuits including the VFO. This ultimately will result in loss of both receive and transmit. You can easily see this by studying the TS-520SE schematic.

I recommend you thoroughly inspect the IF Unit board around the filter area for possible solder shorts and broken leads to the filter select diodes and/or other components that could have occurred during filter removal.

I had a similar issue when fixing a bad TS-520S CW filter installation for a fellow ham, one lead of the filter select diode was broken but not enough to have initially noticed it. I found it by poking around with a plastic stick.

Jon,

Why are you looking at the SG switch and checking the final amplifier's grid voltage?

You said the 520SE was working fine "until" you remove the CW filter. I believe your words were:

"this problem started when I removed the CW filter..."

so why look at the final amplifier? If the 520SE was working fine "Until" you remove the CW filter then the final amplifier has nothing to do with this problem. You also said both receive and transmit were affected "after" you removed the CW filter so the SG switch would have nothing to do with this problem.

If you have not installed a CW filter back onto the IF Unit board you should also check the CW/SSB filter jumpers, see page 32 in the TS-520SE operator's manual for details, so they are back to where they should be when only a sideband filter is installed.

Mike, I switched off the SG for safety which checking the tubes voltage. I replaced the SSB wire from the CW terminal when I took out the CW filter. To test the PA, I of course switched the SG back on. And following your earlier suggestion I have studied the service manual for the TS-520se downloaded from BAMA. To check the connections etc. I loosened the IF board (which houses the CW and SSB filters) this is X48-1060-01 and it connects with board X54-1080-10. I have found the IF board circuit diagram in the Manuals schematic but not that of X54-1080-10 ! There is a lead marked (OUT) on the rigs X54-1080-10 board which goes to the IF via a small coax but the inner and outer of this coax show a short circuit when I check it with a meter on the IF board as the outer of the coax is earthed. This cannot be right. The other connections on the IF board are all OK. Can any good person put me in touch with a schematic for a TS-520se where it has a X54-1080-10. On the actual rig, this board is vertical on the same side as the BIAS, VOX, etc adjusters.
I don't think I have missed it on my schematic....but probably been looking too hard and it's there all the time.
Regards

How about a piece of heat shrink? The clue to if the case is hot or not is if it is in an insulated mount from the chassis.

Subject: [TS-520_820_530_830] Re: HAZARD AWARENESS

I am glad that Terry brought this hazard to everyone's attention. I have those Nichicon aluminum caps installed in my 530S and accidentally touched the aluminum top of the first one in series and got a real scare. Measurement with my DVM from the top of the cap to ground gave something like 375 volts! Since then I have cut a piece of yellow self-adhesive insulating tape into a round circle that just covers the aluminum surface.

Terry, I've been pretty busy around the house lately. Hopefully I can get back to the bench today. A local ham gave me watt/swr meter that he checked against his bird to make sure that it was reading correctly. I hooked it up last night, and it seems that the radio is indeed putting power out. I'll go back over each band today if I get the lawn mowed :-). I also want to go back over the alignment procedure to make sure that I didn't make any mistakes.

OK

A known good in line wattmeter is a real asset for loading and troubleshooting. RF meter position works fine for loading, but it is relative power. It wont tell you if you have very high VSWR (open) or if tube emission is down.

A wattmeter puts a real number to the RF relative power meter position.

With nothing connected to your hybrid the RF meter position will still indicate because essentially you have the 11k ohm rf voltage divider resistors in shunt with your Plate Loading capacitor serving as a load and there will be rf voltage IR drop across them. Can fool you into thinking you have RF output power. So the wattmeter shows you actually have RF output to the connected dummy load or antenna system and how much the power level is. Should see approx 100 watts at approx 200ma to 225ma of plate current into 50 ohm resistive load. Depending on the model and rig less on 10 meters (80 to 85 watts).

Alan,

The reason your ohm meter is displaying a short across the SO-239 and coax pig tale is the RF choke, L4, is connected between the antenna center conductor SO-239 and ground. This is NORMAL and should NOT be considered a problem.

Do you have the TS-820 operator's and service manuals? If not then I recommend you download them and studying the schematic. You can download them from my website

Not sure about the 520S, but on the 820S the alignment starts with 160m and the service manual procedure includes adjusting IF board T10 and RF board T1 along with the 160m TX coil.

I went through a trouble shooting period where ALC indication disappeared during alignment and subsequently could not finish alignment, could not get an ALC drive peak when tuning, and could not get more than a few watts tuning in CW mode.

Since initiation of ALC indication is dependent on exceeding a sufficient RF drive level, I measured RF drive with my VTVM at the finals board DRV terminal (blue wire entering at the corner) and used that as a substitute for ALC during alignment of 160m TX. Switching the meter to ALC after finding the RF drive peak on the VTVM showed that ALC indication was restored.

This recovery occurred when I found that RF T1 was off.

The low band alignment is done first because it sets up the influence on the upper band alignments...

I'm wondering, is it possible that your low band is misaligned, but your high bands are also misaligned so that they actually have power while the low band does not?
It is not clear if you attempted the alignment or not... VFO in your video is set to where you would if you did... ?

Hi Guys,

I am in need of some advise.

My TS-830, from the day I purchased some 14 years ago has always had to be tuned 1Khz lower than the actual freq. So if a station is on 14.200, I have to tune the dial readout for 14.199Mhz.

I tested this using my TS-480 and a couple of other rigs I could get my hands on over this time.

I don't have a freq generator, so cannot test it that way.

I have zero beat it to WWV on 10Mhz, and confirmed the 1Khz off.

There must be a trimmer in there so I can adjust it and bring it back on to the correct readout?

Regards

Kevin, ZL1KFM.

Kevin,

Ther is a section in your user manual that will allow you to under take the digital display conversion.

Connect the antenna and set band to recieve 10MHz WWV and adjust vfo until a low frequency beat is heard. Turn 25KHz calibration marker on. A two beat signal will be heard (double beat) both high and low.

Adjust the IF shift for low AF response

While receiving double beat, using an insulated tool, adjust the standard oscilator trimmer through the reference adjustment trimmer, on the bottom of the radio, (radio should be on side in service postion), if unsure refer to your user manual for location. Adjust the trimmer until the two beats are heard as one. This should be done 2 - 3 times on a radio that has been switched on for warm up period. Once you have done this 2 -3 time your digital calibration will be completed and should be on frequency.

If you can get hold of a calibrated frequency counter, I would also check the 10MHz reference oscillator on the PLL board.

Any problems report back for further assistance

73s

Dave

There is another way to to it today.

Back in the day we needed a crystal calibrator and an international time and frequency station such as WWV or CHU but today not so much. Even with WWV it still requires good propagation to use them in order to hear the zero beat and the closer you get to zero beat the lower the audio level and the human ear frequency response rolls off.

If you have trouble with the zero beat method can try using the the SSB switching method by flipping back and forth between LSB and USB until the 600hz tone that is transmitted on alternate minutes sounds like the same frequency. Easier for the ear to differentiate this than true zero beat.

Today with all the modern DSP rigs on the ham bands that are dead on frequency and so many strong Net operations like 14.300 maritime mobile or Midcars 7.258 and Ecars 7.255 you can just simply tune on the Net of choice and tune for a natural voice and then adjust 10 mhz counter reference trimmer cap TC-1 until the digital display reads same as the Net frequency. Can get very close this way. Of course this assumes that your VFO has been calibrated to track at 50 and 450.

Lastly, if you have a close friend whose natural voice you are familiar with and he has an unmolested modern rig you could also have a QSO and adjust the trimmer on his transmission.

I am assuming there must be some popular strong copy Nets in New Zealand that could be used. If not, then as Dave suggests you will need to use WWV or a calibrated frequency counter.

Just a quick hi. I just picked up a TS-830S and it's deaf. I can hear a little faint hiss from the speaker if the RF & AF gains are at max. I found a copy of the service manual and survival guide (among other stuff) & will be digging into it when I can. Gotta say it's a nice looking radio. From what I've read, it's a real performer. Other than the 830, all my stuff is older Heathkit things like an SB-102, HX-10, RX-1 as well as a Hammarlund HQ-170,180 & 215. I'm really anxious to get the 830 working. I'm building an engine for my Mustang now so the shop is kinda crowded. Soon... Real soon <fingers crossed>.

I went and picked up my TS520SE yesterday from my mates place, 244klm away, and couldn't help myself. This morning I plugged her in, let it warm up then folowed Alans video and tuned her up. Remembering I'm new to these radios so I followed the video to the letter and it tuned up to perfection(165 watts into dummy load) and had to turn it down to 100 watts(all I'm allowed). I later spoke to my mate and got a rock solid report, one other station said it's the best he's heard me on air. During the 30 minute QSO I never had to touch the VFO it stayed solid on freq. This radio until 1 month ago had never been plugged in until my mates variac. I really love these old valve radios

165 watts into a dummy load with a TS-520SE? Not possible!! The TS-520SE final amplifier (Final Unit) and power supply (Rectifier Unit) are not designed to nor can it provide the necessary voltage and current demands to produce that much output power.

It would be interesting to know what the "IP" meter and the "HV" meter indications were with 165 watts into your dummy load and watt meter???? I would check your dummy load and watt meter because, as I said above, the TS-520SE is not designed to produce 165 watts output.

Neil:

Even if the rig has been QROd and there is 300vdc applied to the Screen Grids about most I have ever seen is 140 to 145 watts output @ 300ma. This is very hard on the radio. Hard on tubes, hard on the power transformer, hard on the RF Plate choke.

You could do a visual in the PA cage to see if the RF Plate choke is burned/discolored and of course could measure the Screen grid voltage at the 6146 tube sockets and at the 12BY7A Driver tube socket.

I am a little reluctant to tell you to do these things as I would seem you are relatively new and there are lethal voltages inside the radio.

Lets just hope rig has not been hot-rodded and that your wattmeter is not accurate .

One thing with Allens video he forgets to have you go back and check Ip (plate current) after he loads to maximum Relative Power (RF position of the meter). That is a must to ensure not exceeding much more than 200ma on a TS520.

Check to make sure that either the Remote VFO is plugged in OR that the Dummy plug is plugged in. This bug bit me a couple of weeks ago on a rig I got at a Hamfest. Once I knew to look for it, I discovered that the dummy plug was missing. It turns out that pins 8 and 9 have to be shorted for the internal VFO (an a couple of misc LED) to get their power.

The seller didn't include the plug and I didn't have a replacement. I just opened the hood and soldered a jumper in. If you are timid, as was I, use a clip-lead to prove to yourself that the missing jumper is the problem and then solder the jumper.

The rig works great now.

Neil,

It's great it works after all this time.

I agree with both Terry-k9tw & Mike-w5rkl. First, I doubt the accuracy of the watt meter you are using. You can do some simple math: P(power) = E(voltage) x I(current). The "E" value and the "I" value can be obtained from your front panel meter...this will give you INPUT power to the final amplifier tube(s)..and figuring an efficiency rating of...say a nice round 50%(slightly more really)...you can do the math to figure the "output" If I remember, the 520 series is rated at 200W PEP(SSB) and 160W DC INPUT. So, say you have a full 160 W INPUT, and a final amplifier efficiency rating of 60%...you end up with about 96W OUTPUT..which is right on target as far as output goes...you may get slightly higher output on the lower frequency bands...and slightly lower on the uppermost ones. Hope that previous owner did not "QRO MODIFY" it...that's just wrong...as the power transformer, final amplifier tubs, plate choke..and other things you don't want to destroy...will get damaged.

Good luck, keep us posted...ask questions if needed

Ken,

The 830 series does not have the same VFO plug that the 520 & 820 series do and thus, does not need a "jumper" as previously described. Many faults can happen to cause your problem. Do you know the history of this rig? Prior owner may have got a lightening hit..inadvertently transmitted INTO the rear antenna connector..part of your voltage supply on the rectifier board could be missing...and on and on. See if you can hear anything from the remote speaker jack on the back. Good luck luck on your engine rebuild. When time permits...let us know more..especially your ability and equipment available.

Kevin,

Do you have, or can you borrow a frequency counter? If so, check the VFO adjustment on Pg 34 of the Service Manual. This is what Terry-k9tw was talking about...the 50 and 450 tracking. These "adjustments" are made through the TOP of the VFO under the silver tape. See Pg 42 of Service Manual for location. It makes it easier if you remove the 4 "allen or hex" screws holding the VFO in and slowly & GENTLY remove it...There is usually enough slack in the connections to get full access...just be careful when putting it back in...no pinched wires!

Hi all,

I am a relatively new ham and have just gotten my first radio, a clean TS-820. I am in a very strict townhouse situation and am trying to figure out the best way to get on the air. I was thinking about an Alexloop that I could setup and take down as needed but their maximum power is about 25W. I was wondering what steps I would need to take to limit and monitor the output power. I know this is probably a silly newbie question but I want to make sure that I don't harm the antenna or radio.

Thanks,

Ryan - W3RMD

300 bucks for a short piece of wire and a few spreaders and a LOW power tuning box,
 some one is getting rich with this ???
Just hide some wire around your roof and do a lot better !!! turning down your power on CW is easy but not so easy on SSB mode on a 520 etc. Turning down youl power with a stealth mini antenna is not going to get many QSOs ! .

I second John’s comments. A loop is a very inefficient radiator; more suited for a receive antenna on the low bands than a general purpose transmit + receive antenna. The transworld backpacker is about the same price, will take the 100W from the 820, and will work better (IMHO) than the loop for the bands where the action is (20m) for the limited space challenge. And it will sit on your patio not giving anyone in the neighboorhood any heartburn.

The TS-830 does not have a requirement for a remote VFO socket jumper plug.

The only Kenwood hybrids that require the jumper plug when the remote VFO is not used are the TS-520 (all 3 models) and the TS-820 (both series) transceivers.

The TS-830 remote VFO socket is an 8 pin DIN with an embedded switch, identified on the TS-830 schematic as S21. S21 controls the application of the VFO's "B+" which is +9VDC. If this switch is stuck "Open" due to dirt etc then the internal VFO will not have any B+ and the digital display will be "dark" resulting in loss of both transmit and receive.

If the digital display is dark, try giving the remote VFO S21 switch a shot of contact cleaner then insert a few time, a 8 pin DIN plug, follow the cleaning process with generous amounts of canned air to remove any/all dirt and contact cleaner residue from the DIN socket and test for operation.

Ryan
I lived in a condo and put up a wire dipole on 15 and 20 meters stapled to the top of the patio cover and worked great DX with my TS-820 at around a 100 watts. Another time I lived in a second floor apartment and put up a 20 meter wire dipole, thumb tacked at the top of the wall next to the ceiling. I used RG-8X, a balan and a BNC connector to bring the coax to the TS-820 mounted in a linen closet. Worked great for a few thousand miles. I just tuned the antennas for the phone part of the band and they worked great. No tuner required and no complaints.

I've got a used Heathkit HM-102 coming, I'm sure that'll tell me the truth. The radio as I said had never been plugged in, it was purchased then he passed away before he could use it so it's dead stock. It sat at his house in it's box for years before a mate called and asked if I wanted it (as if I would say no). I did the tune up on the dummy load then as my mate(whose got 2 TS520S) said to just check it again when it goes to the antenna. I've used it all weekend and it stayed rock solid on freq and never missed a beat. I checked tune-up a couple of times during the day and everything was sweet and still has that new radio smell. Being new to these radios the cover stays on until somebody who know better comes around, rather be safe than sorry. Anyhow I'll keep you fine people up to date and Thanks again for all your advice.

Neil,

Just in case your HM-102 does not come with a copy of the manual I have the HM-102 manual and the QST article that modifies the HM-102 to become a Peak Reading watt meter. Both files are on my website at the following link:

http://w5rkl.com/manuals-and-documents/

Click on the above link and scroll down the page to the Heathkit section and click on the 2 files. The files will download to your computer. Save them to a fold so you have them.

I have an HM-102 and it works very well. Have fun.

Here are some choices, based on lots of theory and many years of experience:

-- Use a half-wave antenna, such as a dipole. An RF ground is not needed in this configuration.

-- Use an OCF (off-center fed) antenna. This might fit the geometry of your property better than the half-wave antenna. An RF ground is not needed in this configuration. You will need to use a balun and/or UNUN to isolate the antenna from the feedline. (I use an 80 meter “single band” OCF for 80 meters because it fits my lot better than a dipole.)

-- Use a 1/4 wave antenna, such as a vertical, with a counterpoise. There is no way that you are going to be able to use the earth as your RF ground from a second floor shack. You must use a counterpoise and should try to run it as far from your shack as possible to reduce RF in the shack. Hang it out the window if possible. It is likely that you will have to live with some RF in the shack.

--- Use an end-fed antenna. Again, there is no way that you are going to be able to the earth as your RF ground from a second floor shack. As with the 1/4 wave, you will need to use a counterpoise. You will also need to deal with feeding the high-impedance end, which often requires a rather robust transmatch or large loading coils.

Forget about trying to use the earth as your RF ground.

49086. VFO-230 Diode

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-23 17:00:20 UTC
From: Stephen Gilbert
Topic: 49086 Message: 49086

I am repairing a VFO-230 and have to replace D11, which is not shown on the schematic, but is in the voltage multiplier circuit for the -24v line. This diode marked W110,is short circuit, but can find no information on the web about this diode ratings, what it is or anything I suspect it may be a zener but no proof of this. I have temporarily replaced it with a 1N4007 which has got the display working again, but it is rather bright.

Anyone know what a W110 diode is??? I suspect that the full numbering is not shown like in a lot of Japanese semiconductors.

Ken,

I agree with Mike-w5rkl, about checking/cleaning the remote VFO socket, listed as S-21. This is a very small micro switch that is part of the socket. Since the rig has not been operated for years and has just been sitting around...this would be a very simple and easy place to start.

Stephen,

It is a Zener and the part name is WZ-110, part # V11-4161-46. It is on the F2 line (pin 2, connector 3), not the -24 line (pin 3, connector 3). I can see it on the circuit board X-ray views right next to R20 (220 ohms) but it doesn't appear on any schematics I have looked at so far. The same part is used in a couple other rigs but the voltage at that point in the circuit is not marked on any of their diagrams.

I suspect removing that 1N4007 you installed will have no effect as it is, effectively, not in the circuit and the full, unregulated voltage is being supplied to the display tube. I also could not find the voltage for the display tube (9-BT-12, pins 1 & 28) which would have provided a clue. Although the circuit used in the TS-830 is not identical you could measure the voltage used on its display as a guide.

Have you measured the voltage on that line at the point where the diode connects? My son has a VFO-230 but it is two hours away from me and he can't look at it now to take any measurements. Until you get the proper Zener you could experiment by inserting different voltage Zeners (watch the polarity!) until the display brightness approximately matches that of the TS-830.

Good luck and keep us posted!

The NTE replacement for the WZ-110 is an NTE-5020A, 11 volt zener.

Check NTE's substitution webpage

http://nte01.nteinc.com/nte/NTExRefSemiProd.nsf/$$Search

and enter

WZ110 in the search box and press RETURN on your keyboard or click the
"SEARCH" command button.

49091. VFO-230 diode

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-23 20:18:42 UTC
From: Stephen Gilbert
Topic: 49091 Message: 49091

Thanks for the info on the diode guys. Yes - I agree that the 1N4007 I have put in will have little effect. I did some tests on just the power supply board and noticed that the voltage drops quite a lot from the offload 39v, (it was that high because there was no zener), to around 27 volts with only a small current drain, but there is no details of what the display tube and drivers consume. Anyway, I will replace it with an 11v zener and get it correct.

On mods.dk, there is a corrected circuit of the voltage multiplier, as the original schematic is wrong, and D11 is omitted, and not even listed in the component list.

I have repaired several VFO-230's (I've got three of them) and the power supply soldering in each one is terrible. In each case, components were loose, and in one case R10, a 270 ohm metal film resistor fell out as I turned the board over. I have replaced all the electrolytics in the PSU and by replacing the capacitors in the voltage multiplier circuit, it cured the flickering display. I do not understand why they made the power supply board so small with all that heat from the regulators and the large resistors right next to the capacitors, when there is plenty of space in the case for a bigger board. However, it has worked for around 30 years.....

Thanks again, Steve, G3OAG

49092. TS-830 remote VFO socket

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-23 20:31:54 UTC
From: Stephen Gilbert
Topic: 49092 Message: 49092

Hi guys...as has correctly been said, there is a switch integral with this socket, but I have found that it can become very unreliable. On two of my 830's I drilled a small hole next to the socket and put in a miniature changeover switch, to replace the socket internal switching. If I remove the external VFO, I just flick the switch over. This has got over the problem of the unreliability. The 8 way DIN plug/socket pair are very poor connectors anyway, and often I have to squirt some switch cleaner in to get proper operation of the external VFO. You occasionally get the L900 reading in the external VFO, after doing an A=B split operation, showing that the 500khz is not getting to the VFO.

One of these days I will replace them with something that is gold plated!!

Steve, G3OAG

Stephen,

If the D11 you are looking for is located on the Digital U it Board (X54-1570-00). My parts list says it is an 1S1587 Diode. I hope this helps.

Walt, KA2NJF

Subject: [TS-520_820_530_830] VFO-230 Diode

I am repairing a VFO-230 and have to replace D11, which is not shown on the schematic, but is in the voltage multiplier circuit for the -24v line. This diode marked W110,is short circuit, but can find no information on the web about this diode ratings, what it is or anything I suspect it may be a zener but no proof of this. I have temporarily replaced it with a 1N4007 which has got the display working again, but it is rather bright.

Anyone know what a W110 diode is??? I suspect that the full numbering is not shown like in a lot of Japanese semiconductors.

Stephen, G3OAG

49094. Re: [TS-520_820_530_830] VFO-230 Diode

Yahoo group: TS-520_820_530_830 (2014)

Topic: 49086 Message: 49094

Ken:

The TS-830 uses "high" frequency ac (approx 220hz) to supply the filaments (as opposed to 60hz) and it runs around 4.0vac. If you read it with a DMM depending on the DMM AC frequency response you may read approx 0.75vac. A typical VTVM on AC range will usually read it close to 4.0 vac which is more accurate.

The filaments are directly heated so they are the cathode of the VFD tube (operates a lot like a triode tube).

I suspect the zener you are discussing is the one used to set the filament cut off bias? This zener sets a DC offset to swing the AC filament voltage around above ground. Has to do with preventing unwanted illumination.

I dont have any notes on the VFO-230 heater supply. As I recall it uses a step down transformer which is different than the TS830 T-supply oscillator, but been long time since I have worked on one.

From: Ken Winterling
Topic: 49086 Message: 49095

Terry,

Thanks for your input. I was working from a pieced-together schematic on my small tablet but it sure looks like one of the secondary windings of the power transformer is connected directly to the two filament terminals of the display tube. That would make it 60Hz. I thought the high frequency was generated in the DC-DC inverter that generated high voltage for the display tube.

Regardless, I need to work with a bigger road map since the power supply parts and display are on opposite sides of the diagram and on different pages. It is difficult to scroll back/forth and up/down and keep track of the circuit.

I don't have a VFO-230 handy to make any measurements and no notes on the ones I have repaired cover the display or this diode. The ones I have fixed did not have display or display power supply issues and none had a failure of this particular zener.

Now he has me curious. I'll have to dig out the large schematic and see how this works.

Wow, the solution to the deaf receiver problem turned out to be quite simple. The little coax cable that goes to the connector labeled VFO on the RF board was disconnected. Duh. With a 3 foot test lead for an antenna, I already heard WWV and some QSO's on 40 meters. I haven't hit the filament switch yet. Think I'll wait until I can get a proper antenna connected (or a dummy load). I checked the ESR on the two large caps and got 0.14 ohms so I think they are ok. This is a nice looking rig. The display is bright and the accuracy seems fine. I don't know how it compares to other rigs but I have a nice R-390A to check against. I have a D-104 and/or an EV 638 mic waiting to be connected as soon as I find a 4 pin plug.

I appreciate all your suggestions. I've noticed a couple of solder jobs that don't look factory so I may not be done yet. I'll definitely check the remote VFO socket.

Also check the displayed freq on the 10-meter switch settings to make sure they are not modified for CB. That's how I found out there had been a chicken-band hack done to my rig. The wrong freq was displayed, and it required replacing the crystals with the correct ones. Not such a difficult task, but a touch pricey for the crystals and still quite annoying that it had to be done in the first place for a rig sold to me as "in perfect shape." I have YET to make a QSO on it, since I've not had the time to re-align and get it back within specs after replacing the crystals.

Was sort of hoping to get to it today, but had to take the wife to the hospital after she fell. Passed out, dropped like a sack of rocks right onto the sidewalk, cracked her elbow bone, and got a mild concussion. They're keeping her overnight for observation...

Maybe TOMORROW I can sit at the bench for a couple of hours and run through the manual routine for checking the alignment and calibrating this poor thing,

Maybe. And maybe pigs will fly by while I'm doing it, what with my luck. Oh well. C'est la vie.

That is what I was trying to tell you. However, I did have a typo slip in. Should have been 22khz and not 220hz. The TS830 display filament is AC pulsed fed at 22khz so that is why you will get a funky reading if you use typical DMM to read filament supply voltage.

The TS830 supplies the filaments off the dc to ac inverter (T-powered oscillator) transformer and the frequency is approx 22khz square wave at approx 11.0vac P-P or approx 4.0vac rms. Best to look at filaments with an O-scope.

Also, there is no real "high" voltage supplied to the display tube anodes or grids. Grids run around -17vdc to -18vdc and anodes run from approx +12vdc to +20vdc.

If the zener diode you are talking about is the filament "cut off bias" zener then if wrong value is installed could have some background illumination (ghosting) when segment anodes and grids are not being addressed. You want to keep the filament/cathode raised or floating sufficiently above ground so the proper zener voltage is important. So experimenting with different value zener diodes you would have to know what to look for. If this is the diode that he found bad I would stick with the NTE 5020A zener that Mike suggested or any 11.0vdc zener sub. Kind of unusual for it to fail.

As I mentioned I dont know for certain how the VFO-230 supplies the VFD display tube filaments. I thought they just used 60hz via line transformer. So point of my first response was that you may not be able to make voltage comparisons between the TS-830 for troubleshooting. I may be wrong about that. I should have found a good copy of the VFO-230 schematic and studied it to confirm any differences between the two circuits before I made any comments instead of trying to go from memory.

If you want to see something interesting Google on regenerative receiver using a VFD. There are people who have recognized that a VFD is a triode tube and have used it to build regen receivers. Also you can find a You Tube video that shows use of a VFD as an audio amplifier for a crystal radio. Cool stuff!

Hi Ken,
My 2 million SN 830S checked good for ESR also. But even so, the first of the 2 HV caps lost it's will to live. It did not blow up, tho. So you know, just because the ESR is low, does not mean it/they won't fail in the near term. That was a learning experience for me.

Bob

I am not a VFD display expert.

As I understand it has to do with multiplexing and annoying display flicker. The human eye wants to see a solid display. Mfg/designers pay attention to the relationship between the frequency of the grid refresh rate and the filament/cathode frequency to avoid certain beat notes.

I use to have a good VFD primer that Futaba provided, but cant seem to find it.

Of course DC can also be used for the filaments of VFDs used in portable battery powered devices.

For long life very important to have correct filament voltage level. The filaments are tungsten wires coated with oxide coating just as in our vacuum tubes and too high filament voltage will accelerate evaporation of this coating.

I have had couple of KW hybrids on bench that had dim displays and I first measure the filament voltage from pin to pin (approx 4.0vac) and from pin to ground (approx -12vdc). Remember for proper operation the filament is floated above ground to prevent ghosting thus the need for that zener diode we all keep talking about.

If I find the ac and dc filament voltages to be in spec then couple of options. Can boost the filament voltage a little to see if display gets brighter. If it does then next option would be to try to rejuvenate it. Kind of like the old days of TV CRT rejuventation. Can use bench supply and run higher current thru the filament for short time. Slowly ramp filament voltage up until see the filament wires glow bright red. Hold for 5 seconds or so. I repeat this three times. Cant do this without accepting some risk. Might get a nice normal brite display when done and could burn out the filament. Of course you know the display tubes are no longer available. I have couple of spares for my personal rigs and guard them!

Suspect more info than you needed.

Bob:

I am firmly in your camp. I ESR all the HV caps and the 300/210 caps on all KW hybrid models that come across the bench. I do it more for academic exercise and compare results to what the rupture vents look like. It is interesting. See some vents that are swollen and convex and cracked and maybe white crystalline deposits and still have good ESR. Of course the ones that have puked brown black tarry liquid dont get ESRd!

I always recommend to all owners that they authorize at minimum changing the HV caps due to the collateral damage they can and will cause when they fail. Some decline but most tell me to change them. I have changed them in all of my personal KW hybrids. After 35 years they dont owe me anything. Cheap insurance.

Hi Bob,

Yeah, caps are often the weakest part of electronics components. In my real job, I repair medium to large UPS systems & inverters. When I check caps, I measure value, ESR and leakage. I have a nice old Sprague TO-6A which has found its share of stinkers.I just got this rig 5 days ago so I'm just starting to go thru it. Thanks for the tip.

I agree Terry. I think folks should consider the following:

1. Save a few dollars on a repair bill by not replacing the original HV filter caps then hoping any failure in one or both HV caps will cause the fuse to blow and save the transformer and other components

or

2. Spend considerably much more, quite often twice to three times as much, replacing the power transformer with a used transformer ($100 or more) or having the original power transformer rewound ($188 plus shipping both ways by Tripod Transformer Rewinding Service)

Number 1 is a huge risk which can easily lead to item 2.

Just my 2 cents worth.

Just in case any TS-820S owner is following this here are my notes on the LD-8109 VFD display tube filament voltage and the cutoff bias zener diode.

1. 5vac P-P
2. 1.8vac rms
3. 13khz square wave
4. DC offset (bias) -20vdc

The cut off bias zener is interesting. They employ two diodes in series to establish the required cutoff bias. D16 BZ-220 22 volt zener and D17 SV-03 2.1vdc silicon diode (this device is three silicon diode junctions in one package) so the two diodes in series provide the 20vdc zener voltage. Some people think that the SV-03 is a varistor and it is not.

Of course the LD-8109 VFD is no longer available and I have never seen the LD-8135 sub either.

Never had a bad display tube or supply voltages on a TS-820S however I work on far fewer of them than any of the hybrid models. My personal TS-820S DG-1 remains flawless (now I am jinxed!).

Mike:

It is funny the logic some folks apply. I would much rather replace HV caps than my power transformer any day. There will come day when wont be any pulls or folks rewinding them.

Some folks who buy their first Hybrid never look at the fuse. I had a TS-520S here last week that had a 250volt 20 amp fuse in it! I see all kinds of non standard fuses. Time delays are most common.

I understand discretionary income limits, but when rig hits my bench you have already incurred $100 in round trip packing and shipping cost, the rig is open on my bench, you sent it to me because you apparently have some level of trust. Why then not take advantage of this opportunity to replace the HV caps especially when I tell you that the rupture vents are not normal.

Of course I am very appreciative of the business, but hate to send it back with the caveat that I cannot warranty any subsequent work that may be required as a direct or indirect result of capacitor failure. Collateral damage is pretty common.

I misspoke. It was an automotive fuse. It was 32vdc at 20 amps and not a 250vdc fuse. Never sub and automotive type fuse for the factory original and never up the amperage.

Yep, been there. I recently purchase a Drake R4A receiver that had a similar problem, blown power transformer (high voltage secondary winding was shorted). The regular fuse rating specification is 250VAC at 3/4 amp slow blow but a previous owner, for some unknown ridiculous reason, put a 4 amp fuse in the holder. I knew the receiver had a bad power transformer when I bought it so no surprise there, the seller and I were talking via email before I purchased the receiver from him. I was very lucky, I found a company in Grand Haven, MI, "Hayboer Transformers", that made me a new, not a rewind, power transformer made from the specifications of a Drake R4B power transformer. The newer 6K series serial number R4A power transformer has the same specs as the older R4B power transformer.

So the next time the repair tech asked if he should replace the HV caps, tell him yes. You will be glad you did.

A 40673 makes a great sub. Try Scotts Electronics (crystal set supplies). He was selling NOS ones for $6.00.

Can also find the 3SK22 on Ebay from foreign suppliers from time to time. Lastly a NTE-222 will work. Both of these will be closer to $15.00.

Perhaps it would be worthwhile to check out some more modern devices.
Some discrete FET's in plastic packaging have better performance and can
still be easily obtained. 3n222's are VERY rare these days and very
expensive.

Thanks for all the great suggestions all. I am still going through everything trying to figure out my best option. I went outside today and took a few pictures of the area I am trying to get setup. Hopefully someone can give me something workable. Unfortunately, I have a strict landlord. They won't let us put any screws in the walls and we can't even paint -- I don't even want to ask about an antenna.

As you can see from the pictures, my window is right at the apex of the garage. Whatever I do I have to keep it to our side. Looking out the window I can't go to the left as that will be visible from our neighbor's porch.

49124. TS-820S Carrier Unit CAR-2 CW(T) TC-1 trouble / advice

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-25 10:27:12 UTC
From: paul.nussbaum@...
Topic: 49124 Message: 49124

Good morning all,

My carrier unit has been acting up. I initially had RX in USB and LSB go down to very low volume so I removed the unit, disconnected the two boarda from each other, and disconnected the connection of the lower board to the rest of the radio, reconnected everything and checked the little side connection with the loop... After that, USB and LSB RX came back strong, so I think it was the connections.

Now, I have the leading 9, 21, and 29 on the display when in CW TX...

I just pulled the CAR-2 board and tested continuity across TC-1 and found it is conducting, whereas TC-2 and TC-3 remain open, so I think TC-1 is the failure for this.

I am an absysmal solderer, but I can try to replace TC-1 with another.
Or I could send the board or the whole carrier unit to someone with a 820 willing to do so, which might be better since the new TC-1 would have to be "set" to the right TX offset?

Or maybe someone has a spare Carrier unit or just the CAR-2 board?

Does my analysis sound right that this is the failure?

Any advice on how best to proceed?

TC-1 on the schematic is "p 10" so 10 picofarads?
What else should I know or do?

Thanks,
Paul

Ryan...

Now I REALLY am glad I own a single family house, with no HOA!

After reading about the "no screws" restriction, have you considered checking out the 3M "Command" series hangers and such? They are very good in not leaving marks or damaging painted surfaces. That might allow you to tack up the antenna wiring without worrying with the other "restrictions".

Are you sure you are not measuring R3 to ground? I cant imagine why you would be reading continuity on any of your ceramic trimmer caps?

I dont think in the course of troubleshooting that I have ever measured continuity on a ceramic trimmer cap. Rotated them thru the range multiple times as they can sit in one spot for a long time. Also cleaned them and re-soldered a few.

Are you saying that you cannot obtain 8830.70 mhz by adjusting TC-1? Is that why you are checking continuity?

Have you verified that you have 300mv carrier level at CA-2 and CA-1?

After having our own homes for 40 years, moving to and living in a rental that is also HOA / .CC&R is a really a difficult situation for us.

ANY repairs MUST be done by a "professional". Any improvements become the property of the landlord....now throw into the mix Ham Radio and antennas! Many of my Ham friends are in or facing the same situation.

So, I've got my nice TS-830, IC-7000, 2m/440, and about 5 more rigs.....and face "antenna wars" starting next week...Previously, had a 20m SteppIR and 40-10 OCF up about 30 feet....oh well. Plan to start with an attic "slinky" and see where it goes from there

Bob / WA2JAJ

I forgot to mention if you think Carrier level to the Counter Mixer board is reason for digital display issues have you measured the two signal inputs at the Counter Mixer board? You need CVC (VCO) at approx 900mv rms and you need CCR (Carrier) at approx 100mv. Carrier comes from CA-2 routed to the IF board and level set by TC-1 near Q17.

Let me clarify. If you buy a generic branded 3SK22, (i.e. it has no other markings on the case other then the part number(3SK22), you will have to verify the correct leads. OEM 3SK22's generally (but not always) will have mfr's name or symbol, besides the part number, on the transistor and the original pin designations apply. At least on all the OEM 3SK22's I have, that's what I see. The NTE version and the generic Ebay versions are probably all made by the same Company(s) and just have different product codes.

(I've tried this response a few times but Yahoo Groups doesn't seem to like me. I hope it goes through this time.)

Thanks so much for all the responses. HOA restrictions place a real burden on the ham radio operator but I suppose it also helps us get creative!

I think that the off-center end-fed antenna might just do the job. I have gotten the screen out of the window successfully so I am thinking of picking up an MFJ window passthrough and running a white coax to the corner of the house and garage. From there running a long strip of white wire under the soffet along the length of the garage for the long end and then another above the sliding glass door. I'm hoping that I have enough room along the garage and house for both sides of the end-fed.

One question about the end-fed. With an antenna tuner would I be able to get the one antenna to tune up for multiple frequencies or should I just cut it to optimum for one frequency? I might be able to get away with the one antenna but I don't think I'll have much luck with any more than that.

Terry,

I originally I measured at the solder on the back of the board.

I have remeasured from the front.
TC1 conducts through all these combinations below, whereas TC2 and TC3 do not conduct through any of these:

right back leg to front leg
left back leg to front leg
screw to front leg
screw to left back leg
screw to right back leg

I'm looking at TC1 because the Service Manual Troubleshooting page 40 symptom 1 condition is the display showing 9 / 19 / 29.000.0 which is what happens when I switch to Send in CW /TUN /FSK. The Cause is listed as "no carrier signal comes in", and I'm thinking TC1 is in the CW transmit carrier circuit.

I measured CA-2 on the connector between the two carrier boards.
I'm not finding CA-1.

In USB and LSB mode, CA-2 measures 425mv in both RX and TX on the VTVM ACV 1.5V scale.
425mv x .707 is about 300rms...
In TUN, CW, and FSK, CA-2 measures 425mv in RX, goes to 0 reading in TX.

Thx,
Paul

Paul

The screw driver slot to the front leg should read close to 30K ohms as you are reading across R3 33k resistor that is in shunt with the trimmer. The screwdriver slot is electrically the same point as the two legs on either side.Those three points are one plate of the capacitor and the front leg is the other plate of the capacitor. If you measure from left to right side leg will read a dead short of read from left or right leg to slot will be dead short. That will be the same for TC-2 and TC-3. It is how these ceramic trimmers are designed. Only reason for three legs is mechanical stability.

Perhaps you have a bad D1 switching diode. With board out can check it with ohm meter or diode position of DMM.

Hi ryan, there are some end fed lengths you should avoid where the X or Z is too far from something most tuners can handle on some bands..
The various antenna builder's books have charts of good and bad lengths for random, non-resonant antennas that can work several bnads with a good tuner.
I was a ham when I got my first apartments and bought my first house so I did not have the situation of many new hams who bought housing before they got interested in radio !!
All I can say is M O V E !

Thanks Terry, found trouble with D4 and D5.

I measured 33kohm, TC1 screw to front leg.

I confirmed D1's forward and reverse OK.

I continued to test all the diodes and found a problem with D4 and D5 - neither is passing forward.
The solder point the diodes' forward leads share in common does pass continuity between both forward leads, but neither diode is passing forward to their reverse lead termination traces.

I tested the continuity of the local traces OK.

Did you ever verify that you have 9vdc at CW terminal on CAR-2 board when in CW mode and flipped to Send?

If not you need to do that. That 9vdc is supplied by RLT thru Aux relay contacts. Wouldnt be first time bad/dirty relay contact caused a problem.

Mode switch contacts also involved but seldom a problem.

If you have the "can" out of the rig can power it on the bench to see if can get CA-2 output. All you need is 9vdc to power Q1/Q2 and 9vdc for diode switching. If no bench supply can use 9vdc transistor batteries for this.

Ryan - W3RMD As encouragement I send a little note.

I routinely use an HW8 and a Knwd 830, a hidden LongWire,
in CW mode only, and fairly low power.

I live in a HOA also.
I use a 225' Long-Wire, black wire, along the roof-line and behind the rose-bushes on the fence.
I always use a tuner, the MFJ-941 at first, then picked up a little HeathKit HFT9 from way back!
The LongWire is trimmed by literally rolling up the end 8' at a time, and taping it into a coil.
Have been able to get 80 , 40, 20, 21, at near 1:1.1.
Worked Hawaii on 0.5 W, CW, 20M, confirmed.
This is obviously a Non-Resonant LongWire.
I use a 1:1 current balun and a short run of coax to the tuner,
and have a 30' counter-poise wire run under the edge of the lapboard wood on the side of the house.
No Magic here, just good ideas and cut-n-try and re-tune.

Passing along this really neat idea from a ham contact:
A contact wrote that he had been loading his Rain Gutters, from the bottom end.
The Rain Gutter was not grounded, except by the nails into the facia board.
He has a cointerpoise laying next to his foundation on the ground.
He also has 300W and is willing to heat up the gutter a little.
I run about 3W to 10W and don't want to waste any power.
His Gutters are on he second story roof, and mine are on a first story roof.
I may try a better connection on my own Rain Gutters, right at the ground (instead of at 10' up),
maybe it will work better than the first time.

BTW, my length of antenna brings a lower impedance to the Tuner.
If you accidently cut to an even number of Quarter WaveLengths,
then you may bring a 2000 Ohm to the tuner, and that may be out of range.
In my reading, I have seen istructions to use Odd-Quarter WaveLengths on a LongWire.
That is why I rolled up various lengths of the original LongWire at the Far End,
retuning the Tuner each time, on each band, to see if the multiple bands could be loaded OK.
The roll-up method seems to work.

Well, that is what I did, in general,
and I found that the Tuner made things work very well most of the time.
No Magic here, just good ideas and cut-n-try and re-tune.

If you like CW audio filters, you can check
my local site Yahoo Groups "glene77is_Sand-Box" for an assortment of design projects,

or my website at www. GeoCities.WS/glene77is for documentation.

Thanks for the ideas! I really won't know what's possible and not until later next week when we move there. Also not certain yet where the shack will be...first floor but front or second floor facing the rear. Then I have to fire up the TS-830 to see how it survived two moves and no use for almost a year...

I do have some experience with long wire antennas as I ran with one in the mid 1970's on 80m. Of course, at that time, my main antenna was a tri-band cubical quad with bamboo spreaders up on the roof! Gone are the days..

Terry,

Thanks for bearing with me...

Old business...
I measured CAR-2 CW(T) TC1 for continuity instead of resistance.

After your counsel I measured the readings you predicted that suggest the trimmer is OK.
I measured D1 to be OK (forward and reverse function).

New business...
I measured +9.5 vdc at "9" terminal and CW terminal in Send.

Before switching Send, the CW terminal measures neg (-)2.2 vdc... normal?

I measured 600mv (425mv rms) at CA-2 in REC
CA-2 drops to 0mv in CW Send

Relay visually / audibly appears to be functioning.

Thanks,
Paul

Paul:

I assume you are measuring at Molex connector CJ-2?

Your voltages at Pins 3 and Pin 5 are normal. It would be very unusual for those voltages not to be available at the jumper pins between the two boards, but I would also measure CW and 9 at the 10 pin jumper.

Does Oscillator start in FSK? If it does not then look at diode D3. Should see approx 0.30vdc barrier on the diode test position of a DMM as it is a germanium diode.

If D3 is good then try reheating the solder connections of pins of X1 8830.7 crystal. Can also check D7 but I dont think it is accessible from component side of the board?

Paul

Looking at the schematic if you measure from CW terminal to Cathode of D7 you should be able to see both D1 and D7 junctions so you should read close to 1.20vdc on DMM diode test. D7 cathode will be accessible from component side of the board.

UPDATE!

CA-2 now goes to about 850mv (about 600mv rms) CW Send.
Display works right in Send with correct TX offset for CW.

I must have brushed T1 to knock if off by a minute amount, really sensitive, the correction was just a hair...

Do you have a recommendation for a frequency counter (HF only)?

You need to adjust it for 300mv rms.

You dont want 600mv of carrier osc level.

The service manual says 50mv but that is incorrect. 300mv will give you proper LO injection level for proper mixer action. Too high a carrier level at the Balanced Mod and the Product Detector can result in carrier leak thru. Check C1A (CA-1) and adjust it for 300mv as well.

The Sinometer VC2000 is a nice general purpose frequency counter.
Another good general purpose frequency counter is the Heathkit IM-4100.
I have both and use them regularly.

The VC2000 has a feature that allows the user to test crystals but only
on the crystal's "Fundamental" frequency. Overtone crystals will
oscillate in the counter's test circuit but show only the crystal's
"Fundamental" frequency.

Just my 2 cents worth.

49150. Re: TS-820S Carrier Unit CAR-2 CW(T) TC-1 trouble / advice

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-06-28 13:50:31 UTC
From: paul.nussbaum@...
Topic: 49124 Message: 49150

Well, nothing but troubles now. I guess I'm going to need a frequency counter to untangle things; I think I have multiple things out of whack, hopefully nothing broken.

I tried setting the carriers down to 300mv rms.

I adjusted T1 on Car-1 measuring at IF board TP-5 and checked the same measure from the CA2 connector between Car-1 and Car-2 boards.

I had a note from somewhere that IF TP-6 was C1A, but I found that with the VTVM ground connected to the chassis I got nothing, but with that ground removed it measures 120V ac... not sure what's going on there. The x-ray trace board picture shows TP-6 as "CLR".

I measured C1A at the same connector between the two CAR boards and adjusted Car-2 T1 to measure 300mv.
It measures 300mv in Send, but it measures about 200mv in Standby... is that normal?

Now the display has problems again, is close to expected values for the low bands during Standby, but the last two or three least significant digits don't settle down.
Send stabilizes the display.
Except 160m band - display is blank in both Standby and Send.
The 10m band leads the display with 19.

At first I though the CW filter might no longer be functioning because the pitch of the beat frequency offset of the marker was very high, but it is functioning; it has the sharp meter peak, but the peak s-meter indication no longer aligns with the beat frequency that matches the CW key sidetone... my side tone is 732Hz, but the lowest pitch I get at marker meter peak is a little over 1KHZ.
I tried adjusting the USB trimmer on the CAR-2 board to shift the placement in the filter to set the peak's corresponding audio frequency to the key side tone but can't get close at all.
If I match side tone to incoming signal offset beat frequency, the tuning no longer places the rec signal at the S-meter peak. Likewise, if I peak the meter, the CW TX offset will no longert match the rec signal frequency. The difference between the rec audio beat pitch and the side tone pitch I can't get any closer than about 300Hz..

Paul:

You dont adjust T1 on CAR-1 board to set level at TP-5 on the IF board? Why are you doing that? I told you that the service manual is wrong regards setting the Carrier Oscillators. CAR-1 has nothing to do with CA2 level.

If you read the step and then look at the schematic it should jump out at you. This service manual has numerous mistakes the worse being when it calls out the wrong adjustment trimmer, the wrong test point and the wrong acceptance criteria all in one step.

You can search the archives and find lots of discussion about proper adjustment of the TS820 carrier oscillators.

Look at the schematic and you will see that TP-5 is supplied via CA2 and not CA1 (C1A).

After you adjust CA2 for 300mv rms then TC-1 on the IF board is adjusted for approx 100mv CCR level at the Counter Mixer board. You can measure it at TP-6 but I like to make sure I have it at the Counter Mix board.

At each step in the Service manual you must question it. Look at the adjustment device and test point and acceptance criteria and see if it makes sense to you. When it does not come back and ask. Easy to see if wrong adjustment trimmer and wrong test point is called out. Not as easy to tell if the acceptance criteria is correct without some knowledge and experience. For example you would never expect to see 50mv LO level for the Balanced Mod or the Product Detector. Likewise those who tell you it is a typo and should be 500mv are just guessing. 300mv is the correct level.

From: paul.nussbaum@...
Topic: 49124 Message: 49153

Terry,
Thanks for those. I have read message 30090 before. It makes the same mistake as the service manual, confusing the carrier boards.

Switch to CW mode. With the transmit switch in Send adjust TC-1 on the CAR-1 board, the board on top, to 8830.7 khz and adjust coil T1 on the CAR-1 board to get 0.3 V output.

The other two adjustments on the CAR 1 board, TC2 and TC3, are for adjusting the FSK frequencies in case you are interested.

In trying to understand things, I have collected a lot of information, none of it I trust until I have checked it. I won't be doing anything until I have access to a frequency counter; then I will resume.

Thanks,
Paul

Paul:

Sorry.

I quickly scanned them and saw that they addressed the Car Osc level issues that you continue to struggle with and if you dont adjust them properly you wont need a frequency counter.

I hope you realize when it comes to setting the LSB and USB trimmer caps TC-1 and TC-2 that the frequencies listed in the Service Manual table under Step 2-1 are only a starting point. You need to adjust the "Carrier Point" for proper SSB frequency response. The IF crystal filter response is set so you have bring the Car Oscillators to the filter. Cant assume that the frequency listed in the table is the filter Fc.

Some do that by:
1. Ear (as adjustment has an element of personal preference)
2. By using the Marker, AGC fast, zero beat method
3. By using audio spectrum analyzer software like Spectrogram
4. By using the audio generator injection in the mic line and watt meter method for equal 3 dB roll off.

There are lots of TS820 owners here including Joe our leader who have good knowledge and experience when it comes to aligning this radio. I will let them run with this from this point if you have any other issues or questions once you get your frequency counter. By the way I do agree a Freq Counter is a necessary piece of basic test gear.

Have Fun

Topic: 49155 Message: 49155

Good morning:
I wonder if anyone can help me with the following situation:

After taking the decision to replace the 6146B and 12BY7 in my Kenwood 530SP, due to poor power transmission, which after a few minutes or hours of use and a poor quality audio (like I was talking under water); once replaced the tubes, in my attempt to tune the radio to continue with synchronization, I can see that no power transmission, when calibrating the plate, the needle only moves a little, as also for the load (under 50 40 mA).
Before I change the tubes, I could calibrate correctly, the problem consisted in the gradual loss of power and audio quality, but I finally I could calibrate the radio, but I could see, that I was not getting the real power (approx. 100W) when calibrating the plate.
All this, before change the tubes.

Could you guide me on what I could do o what I could check.

Note:
Experience in electronics: Basic
Electronic bench: Basic
Experience in Hybrid Radios: Basic (this is my first hybrid radio).

Thanks in advance.

Al,

You stated that you had some output prior to changing the 12by7 and the 6146B. After the change, you have no power output. Unless, you have done something else along with changing the tubes, I suspect this should point to bad driver(12by7a) or bad final amp tubes(6146B) May I suggest that you put the old tubes back in, and check to see if they work.

Replacing the final amplifier tubes(6146B) and not neutralizing them, In my opinion, should not keep them from putting out good RF power..IF the tubes are good to start with. Many people make the mistake of changing too many things at the same time...and complicating what is usually a simple problem. Change ONE THING AT A TIME, take measurements/observations, and go from there

Al

Yes you can use another receiver as a rf null detector by sitting it close to your TS530SP. Make sure it is warmed up so VFO is not drifting and S-meter indication wont drift off its peak.

Tune it to 28.800 and peak the S-meter indication presented by the RF from your TS530SP by adjusting the other receivers VFO. Then you can adjust the TS530SP neutralizing trimmer capacitor with an insulated tool to get the lowest S-meter indication on the other receiver.

Make sure you have the Screen Grid switch turned off. If you have problems getting enough signal into the other receiver for a good S-meter indication you can use a piece of insulated wire between the two rigs. Skin one end to bare copper and insert in your TS530SP SO-239 connector on rear panel and then insert the other end with the insulation remaining on it into the test receivers SO-239 connector. You will be capacitively coupling the rf signal from your TS530 into the front end of the test receiver.

If you are having problems loading your TS530SP I would fix that problem before worrying about neutralization of your new finals. You cannot do a good job of neutralizing the new tubes on 10 meters until you can load to full output which will then get the Plate Load and Plate Tune capacitors in correct position for 28.800mhz.

Do all your transmitter troubleshooting and testing on 40 meters into a dummy load and there will be no concern about neutralizing on 10 meters until you have a fully functional transmitter. Your TS530SP wont take off on 40 meters with its new un-neutralized final tubes.

You may be right Terry but synchronizing the tubes just did not make any sense. I suspect the use of proper terminology such as "neutralizing" instead of "synchronizing" would have made more sense.

From: Jan Servaites
Topic: 49158 Message: 49167

Not to write a lengthy tutorial on the subject, I want to mention
another analogy is up in the "light" band. To simplify, consider visible
light waves (can use infrared and way down to 94ghz too).
Look at your better optical lenses. They are coated to prevent
reflections. The coatings are usually the average index of refraction
between air and the optical glass and I think they are 1/4 wave in
thickness at like 550nm wavelength (center of the visible band)
Compare a coated lens to a plain uncoated lens. There's a significant
difference in reflections, something like 9% I think.
Look at an IR lens using visible light. You'll notice how much thicker
the coatings are and not much white light is transmitted through it. Of
course, some IR lens materials are opaque (germanium) anyway and no
white light can pass through at all, and mostly all reflected.
At 94ghz, lenses are made of Teflon and some other materials. For it's
anti-reflection coating, there is none. Instead 1/4 wave grooves are
machined on the lens' surface, so the average index is 1/2 air & 1/2 teflon.

I agree with Joe the simplest first step to try would be to try another known good Driver tube with the original 6146 final tubes. It is more common for the Driver tube to lose significant amount of emission than the 6146 tubes.

Also, what is your plate voltage doing?

You can monitor it by placing the meter switch to HV position. Should see approx 900vdc on the Red HV meter scale. If you see approx 450vdc then you have lost one of the two HV filter capacitors. That could also explain your audio distortion.

It appears you do not have much KW hybrid knowledge or experience. What is your experience level and what basic test gear do you have and understand how to use? Will help members to know a little something about your capabilities.

49173. 830S filter compatibility?

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-01 17:33:12 UTC
From: n612dw@...
Topic: 49173 Message: 49173

Hi Guys,
new to the group, have a question may have already been answered but I couldn't find it if so.

bought an 830 recently to fill out my collection of re-creating my early radio days. pristine condition, S/N 7xxxxxx very late production. Date codes on components are 8620 or later... so it was made I think in the last year of production or nearly so. a real gem.

did find a bandswitch coupler cracked as usual, fixed with new brass one, also replaced the screen and B+ hv caps with new better 105c ones just for grins.

First time I've worked on one of these, very nice construction/design, weakness seems to be the bandswitch.

Superior final cage design where cool air gets pulled up thru the suspended tube sockets up and around the tube from a sort of plenum underneath - better than most, almost like some amps with pressurized plenums like it's supposed to be ! Very happy so far.

Now onto the question at hand....

I want to add CW filters to it. I found the 8mc 500 hz filter and installed that but I am having issues with finding a 455C filter mate for it. There are tons of 455C-1's out there to get hold of, which begs the question....

does anyone know for sure if the 455C-1 will work IF I unsolder it from the plug-in "carrier" and install it in the 830 ???

concerned about physical pinout location and in/out impedances/load etc. My first order guesstimate would be that Kenwood probably just bought the same filters but mounted them on the plug-in carrier board for the later rigs????

best case is that it indeed is the same filter simply mounted in a plug-in carrier board, that I can unsolder and solder directly into and be pin-compatible with the open spot on the 830s.

I'm aware of the inrad filters but want to keep it all stock/OEM if possible.

whatsay yoose guys?

-bob

Bob(please remember to use call sign - if any- when posting)

The filters have SLIGHT differences in center freqs. The pins are the same...and as you stated, one is on a phenolic board...one is not.

You can go to: N6WK.com web site(yes..it's still up and running) and scroll down until you come to the "Kenwood filter spec sheet." I have not tried to interchange them...but a re-alignment of the band pass filter(s), IF trap or both... may be in order to accommodate the 0.7 change in the filters center freq.

N6WK - Gordon(SK) may now be gone...but his web site is still functioning. I do not know how...but maybe surviving family members paid for further web hosting...as it stopped shortly after him becoming SK...then came back up.

49176. Solid State Signal Generator

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-02 14:20:33 UTC
From: Mike W5RKL
Topic: 49176 Message: 49176

I came across this website this morning while drinking coffee and waking up.

http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=27873

http://www.vintage-radio.com/projects/signal-generator.html

The power transformer shown in the signal generator's schematic has a primary voltage of 220VAC. Hammond Transformers could possibly provide a similar transformer with 117VAC primary winding with 16VAC CT secondary winding.

http://www.hammondmfg.com/pdf/5C08.pdf

The PC board could be designed and built using ExpressPCB.com PC board CAD software. I use ExpressPCB CAD software for all my PC board needs. It's easy to learn how to use and free on their website

http://expresspcb.com/ExpressPCBHtm/Free_cad_software.htm

I designed PC boards using ExpressPCB CAD software for the following projects I built:

1. LM741 OP AMP 2 stage audio filter (operates from 9VDC battery)

2. Heathkit SB-400 and SB-401 HV and LV power supply filter capacitor boards (replaced the two 125ufd 450VDC HV caps and the dual can LV cap)

3. Variable frequency 455Khz BFO (variable frequency between 453Khz and 456Khz, ideal for a USB, LSB, or CW fixed BFO circuit or as a 455Khz IF alignment signal source)

A cabinet to house the signal generator and digital display could easily be found on eBay. N3ZI sells a digital display which is easy to build (I built one and took me about an hour to build).

http://www.pongrance.com/ddfc-cc.html

An important note:
The N3ZI digital display has a maximum input voltage of 1.8V rms as stated in the digital display manual. The signal generator DXZone.com signal generator has a maximum output voltage of 3V rms which exceeds the N3ZI digital display input level. A resistive attenuator could easily reduce the generator's signal level voltage down to an acceptable level for the N3ZI digital display. There are plenty of attenuator circuits that can be built quite easily so try searching the web using the phrase

'resistive attenuator"

I'm going to look into building the generator as a fun project. I already have the N3ZI digital display. W8DIZ's webpage is a good source of cheap kits. I built the simple W8DIZ RF amplifier mentioned in N3ZI digital display webpage.

Most email client software has the option to configure a "signature" that is automatically added to every message the write composes and sends. If you are using email client software then check the "Account Option" feature, it's quite possible you can configure your signature to be added "automatically" to every message you send!

I used Thunderbird email client software and it has this option! Thunderbird is free and easy to configure.

Rick,

All of the Kenwood hybrid fans operate on a 100V tap from the power transformer, check schematic. If I remember correctly...the motor itself is wound for 115v...thus a slower fan speed when operating off 100v. I would check the voltage...I have not ever seen a problem like that, UNLESS someone has done some rewiring..or changed the fan to a 12V "computer type" fan and took a supply tap from elsewhere on the rig. The fans tend to be rather quiet..so the owner/op doesn't complain about "fan noise." The fans are adequate for their intended purpose, but extended transmission at nominal power creates lot of heat from these finals. If all else is good...let it go...and as you said: it's lubed up. Many operators/owners do not do this. It only takes a few minutes once, or possibly twice a year to use a FEW drops of a good light weight oil on the "felts."

Update on parts for the signal generator project:

There's a Canadian eBay seller who is selling the dual 365pf variable capacitor for $19.95 plus $4 shipping.

The dual 365pf variable capacitor, mounting bracket, planetary drive (highly recommended), and screw hardware can be obtained from Midnight Science website. I recommend the capacitor and planetary drive mounting bracket for smooth tuning of the generator.

http://www.midnightscience.com/catalog5.html#part2

Futurlec

https://www.futurlec.com/Transistors/BF244Apr.shtml

appears to have and sells the BF244A British transistor used as TR1 for 35 cents each.

Mouser appears to have the BC548 transistor used as TR2 thru TR5 under part number 512-BC548BU for 22 cents each.

I'm still looking for the rotary switch, probably find one on eBay or allelectronics.com.

Fixed resistors and capacitors, disc and electrolytic, can be ordered from Mouser.

Mouser sells the 78L15 regulator (100ma current rating) under P/N 511-L78L15ABZ-AP for 51 cents each in a TO92 package.
Data sheet:
http://www.st.com/web/en/resource/technical/document/datasheet/CD00000446.pdf

Mouser also sells the higher current rated 15 volt regulator under part number 511-L7815ABV-DG in a TO-220 case for 69 cents each.
Data sheet:
http://www.st.com/web/en/resource/technical/document/datasheet/CD00000444.pdf

49181. JIS Screwdrivers – why I've switched

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-02 20:51:27 UTC
From: WQ8Q
Topic: 49181 Message: 49181

I've recently switched to using JIS (Japan Industrial Standard) screwdrivers for just about everything.I got tired of boogered-up case screws and recently acquired a Kenwood TS-440 with screwheads so deformed that it was hard to remove them – resulting in replacing the whole set.There are basically easily acquired sets from two manufacturers, Hozan and Vessel.The Vessel Ball screwdrivers are magnetic and do a great job of keeping screws from falling into a radio.The #2 fits the case screws of the Kenwood Hybrids and the #1 fits the circuit board screws.The Hozan are fine, too, and can be used when you don't want a mag screwdriver.The Vessel kit I have came with a couple of slotted screwdrivers also, which I thought I wouldn't use, but found that one of them fits the knob screws on my TS-820S perfectly.

These screwdrivers will fit ALL phillips screws and will NOT cam out like regular phillips screwdrivers, which are designed to cam out as to not overtighten the screws.

Okay, they're not cheap, but hey, it's a hobby and you're supposed to spend money!

Quite right. The ts 820s fan is really inadequate.
With mine I replaced the original with a 12 volt computer fan run of the
12 volts AC heater rail through a simple rectifier system. Works far
better and my 6146B finals are a lot less stressed. BTW I have also done
some work on the final tank circuit to improve working Q and improve
efficiency. That helps too decreasing
plate dissappation by at least 10 watts.

The 6146B data sheet states,

"To insure adequate cooling, it is essential that free circulation of air be provided around the tube. In most cases, no additional air is required."

"In most cases" is a clever pun intended?

The "Dark Heaters" of the 6146B operate cooler at 1350 degrees Kelvin, 350 degrees lower than conventional tube types. The "weak" fan may have been a design consideration - to minimize noise or the accumulation of dust inside the case, since the fan is barely needed for cooling?

If you spin the un-powered fan with your finger or watch it spin down at power off... if it free-wheels for a few seconds it is fine; if it comes to an abrupt stop it needs oil. The oil hole on top of each bearing housing is very small... one way to get a drop of oil inside is to use a thin strand of wire as a slide guide for the oil drop.

Ignored 1st post but...I feel a discussion coming on. I shall just add that I have run my own TS- 820 for well over 2yrs, 24-7, meaning rarely w/heater off and power is always on. When I do broadcast I have been known to be somewhat long winded! hihi Never a problem with 6146B's or driver in the period and still over 100w all bands but 10m which is about 90-95w. I ran a TS-820S in the 80's same way with never a problem. Really feel my TS-430S is the one with a fan problem! (Slower to come on than I prefer for a transistor rig) No need to brag...they are Kenwoods!

> one way to get a drop of oil inside is to use a thin strand of wire

Or you can stop by your local farm supply place and get a hypodermic syringe and a package of needles (smaller the better, I usually get a 16 gauge needle, works well for most things. Fill the syringe with oil, apply micro-drops where needed. Pin-point precision, really small droplets. It also works for applying minuscule amounts of lubrication on firearms. You only want a tiny bit anyway, to keep dust and gunpowder residues from sticking to the oil and jamming the action.

You might think your local diabetic can provide something useful, but the needles and syringes they use have a tiny, teensy, itty-bitty needle and a plastic syringe; those are MUCH too small for all but the tiniest jobs, and generally the all-plastic syringe isn't petroleum-friendly so the oil will dissolve the seals and melt the whole thing into a real mess.

The syringe I got from the farm supply vet gear aisle has a glass cylinder inside a steel cylinder with a ground-glass fitted plunger. The steel cylinder wraps around the glass parts, which protects it from hooves and being drop-kicked while trying to stab a bull in the butt with an antibiotic or something. Not plastic, and not fragile either. Needles unscrew and can be replaced in seconds, so if you break one off it's no big deal.

This was NOT CHEAP, but mine is almost ten years old now and has been worth the twelve bucks, particularly since I'll never need another one. It should last for a lifetime if I don't get stupid and lose it somewhere.

Well I'm sorry to have to say that my temperature measurements don't support Paul's thesis at all.
The TS820S tends to run too hot in the final in anything like high power. That combined with the rather inadequate Q of the final tank circuit on some bands can put a lot of stress on the finals.
Certainly mine now runs about 15 degrees C cooler on the outer case with a better fan and tuned circuit
adjustments, and better air circulation and I haven't lost a final for some time.
When I first inspected my fan, I was quite dismayed by its inadequate design on what is basically a good rig.
Running it at 100 volts AC instead of a designed 115 just makes matters worse.
IMO it is a very easy and worthwhile mod.

Can you refill it? Or use it to flush parts with solvents instead of oil? Or replace the tip/tube if it gets bent or pinched? Or change from petroleum-based oil to synthetic and back? Or even to a powdered fluid (teflon and graphite) and back to machine oil (after a good cleaning of course)?

If all you need is one sort of oil, that 3M oiler might be a good bet. I won't say a thing against it for that purpose.

But ten or so years down the line I've used my vet syringe and hypodermic needles (actually biopsy blunts when I can get them - no sharp bevel on the end) for all of those things. In particular, being able to shoot a controlled stream of penetrating solvent into a crevice of a piece of machinery (an old time-clock is one item I can remember specifically) can be a real big help.

49190. 830S LSB Receive Issue - VBT

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-04 02:40:21 UTC
From: jblbusa@...
Topic: 49190 Message: 49190

I turned on my 830 after a few months of not using it.

In LSB mode I have some strange behavior and would appreciate advice on what to look into.

LSB audio is overall very low to almost non-existent on multiple bands.

When a move either the IF Shift or the VBT knobs to the right half (from 12 o'clock to 5 o'clock) of the knob position, I loose all LSB audio and the frequency counter goes out. If I turn the VBT back to the left (12 o'clock to 7o'clock) the frequency counter comes back on and audio is back but still low.

Also, if I turn the send switch on the frequency counter goes off.

USB and CW seems find. LSB was working find 2-3 months ago.

Best,
W0HY
Jeff

49191. Took to Field Day and no output

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-04 02:53:25 UTC
From: stg57@...
Topic: 49191 Message: 49191

I packed up my TS-520S to take out to Field Day, it sat in the car all morning while the Club did Public Service with the yearly Bike Race that takes place on Field Day.
So got the rig set up, antenna strung, tuner set with the MFJ analyzer.

Had a few helping hands switching bands and adjusting knobs, after I had it tuned up on 80mtr.

Receive is fine.

Plate Idling current Check - 60ma

Drive Tuning Check - Maximum Deflection

HV Check - 800V in Tune

Plate Tuning Fail - Low needle reading, no dip

Plate and Load Tune - Low needle reading no reaction

Currently less than 20 Watts out shown on the tuner watt meter.

History I have owned the Rig for a number of years, tubes 6146W, regular yet limited use following tune instructions.

All but C15 & 16 of the power supply caps have been replaced with Ken's kit.

PA resistors changed with Ken's kit after purchase, originals looked Krispy.

PA Cage kit on hand, never installed since rig was working fine.

I follow the group loosely and some of the repair tips that are wrote about. I have pulled the case, tubes physically look OK, resistors on PA board look as new, did not check them with the VTVM yet.

Which components should I start checking first? I don't want to start taking things loose and make it worse than it currently is.

Once I have Power back, next step is to clean the wipers in the VFO, as the external one works fine, the internal one is getting spotty where it works or doesn't.

Thanks

WS4JH James

Jeff:

Just for grins place the IF shift at 1200 and VBT full CW. Then try adjusting LSB trimmer capacitor TC-2 (you can access it thru hole provided in the bottom cover). Run it back and forth a few times to clean it and then adjust. You can shine flashlite thru the hole for TC-3 so you can see to get adjustment tool blade in TC-2 slot.

Absent a freq counter and with covers on you can set TC-2 relatively close by placing the AGC in Fast position and turning on the Marker and peaking it with the VFO and Drive control and then adjusting TC-2 for zero beat (slow rythmic motion of the S-meter indicator) around S3 to S5.

If this resolves problem I would remove covers and clean both ceramic trimmer caps on the PLL board with Deoxit and then adjust depending on what test gear you have.

1. Set by ear (helps if you have familiar voice in Rx mode or can use own voice and Moni function)
2. Set using the S-meter-Marker-Zero Beat Method
3. Set by injecting audio into mic line and adjust for 3dB roll off on external wattmeter
4. Set by using audio spectrum analyzer software and noise bridge

Method 3 and 4 are best methods to employ

If cleaning and adjusting TC-2 doesnt fix then for starters measure Carrier Osc frequency and level at IF board TP-3. Need freq counter and rf millivolt meter or O-scope.

Happy 4th

Terry K9TW

Subject: Re: [TS-520_820_530_830] My TS-830 is Always 1Hhz off

Kevin,

Do you have, or can you borrow a frequency counter? If so, check the VFO adjustment on Pg 34 of the Service Manual. This is what Terry-k9tw was talking about...the 50 and 450 tracking. These "adjustments" are made through the TOP of the VFO under the silver tape. See Pg 42 of Service Manual for location. It makes it easier if you remove the 4 "allen or hex" screws holding the VFO in and slowly & GENTLY remove it...There is usually enough slack in the connections to get full access...just be careful when putting it back in...no pinched wires!

There is another way to to it today.

Back in the day we needed a crystal calibrator and an international time and frequency station such as WWV or CHU but today not so much. Even with WWV it still requires good propagation to use them in order to hear the zero beat and the closer you get to zero beat the lower the audio level and the human ear frequency response rolls off.

If you have trouble with the zero beat method can try using the the SSB switching method by flipping back and forth between LSB and USB until the 600hz tone that is transmitted on alternate minutes sounds like the same frequency. Easier for the ear to differentiate this than true zero beat.

Today with all the modern DSP rigs on the ham bands that are dead on frequency and so many strong Net operations like 14.300 maritime mobile or Midcars 7.258 and Ecars 7.255 you can just simply tune on the Net of choice and tune for a natural voice and then adjust 10 mhz counter reference trimmer cap TC-1 until the digital display reads same as the Net frequency. Can get very close this way. Of course this assumes that your VFO has been

calibrated to track at 50 and 450.

Lastly, if you have a close friend whose natural voice you are familiar with and he has an unmolested modern rig you could also have a QSO and adjust the trimmer on his transmission.

I am assuming there must be some popular strong copy Nets in New Zealand that could be used. If not, then as Dave suggests you will need to use WWV or a calibrated frequency counter.

"1. Plate Tuning Fail - Low needle reading, no dip"

"2. Plate and Load Tune - Low needle reading no reaction"

1. Are you saying after peaking the Drive in Tune mode you cannot get the initial plate current dip in Tune mode? If so, where do you have the Plate Load cap set at? Set it so the plates are closed ie fully meshed. This will give you the most discernable Ip dip to adjust the Tank to resonance. If you get no Ip dip then try it in CW mode. Dont leave it key down very long. You may have a problem with the Screen Grid voltage divider resistors.

2, Are you saying with radio in CW mode and panel meter in RF position when you flip to Send and alternately adjust the Plate Load and Plate Tune caps you get no or very low peak in RF relative power? If so, perhaps someone adjusted the RF voltage sensitivity pot accessed thru the side panel. Try adjusting the sensitivity pot for more deflection. 2/3 to 3/4 deflection is good spot to work with.

If you can load the rig in CW mode then will need to measure R5 and R6 56k ohm resistors on the HV Unit board. If one is bad replace both.

From: Mike W5RKL
Topic: 49198 Message: 49199

Robert,

The TS-820 bias should be set to 60ma with the MODE switch set to USB or LSB, it doesn't matter which band because RF is does not play a part in setting the 60ma idling current. Once that is set you should not have to touch the bias pot again unless you replace the final tubes.

You can download the TS-820 high resolution schematic which contains voltages. This will help you compare the voltage in your TS-820 with the schematic voltage. The schematic can be downloaded at my website:

http://w5rkl.com/manuals-and-documents/

Scroll down and click on the high resolution link, the file will download to your computer in pdf format.

It appears from your comments that you replaced "every electrolytic" in your 820 whether the capacitor was found bad or not. That is what is referred to as "shot gun" component replacement which can easily lead to more problems then the 820 initially had. Components should be replaced only if they have been found to have failed through troubleshooting not simply because the component is old.

I doubt the 12BY7 driver tube took out one of your 6146 final tubes. I suspect the 6146 was defective on its own.

Since you said the final amplifier cathode resistors appeared to be burnt then I suspect the bad 6146 had an arc that occurred between the 6146 plate and beam forming element. I have a few videos on my website that discuss this. Click on the below link and go to the bottom of the page. The videos are in "wmv" (Windows Movie Video) format and will play on all versions of Windows without any problems.

http://w5rkl.com/basic-electronic-videos-2/

My suggestion is to replace both of the 6146 final tubes along with the driver tube, neutralize the finals, and providing there are no other problems in your 820, that should fix your problem.

Mike

If he is eating Driver tubes he may want to measure all the 12BY7A tube socket voltages especially screen grid voltages.

I agree with you that the Driver tube didnt hurt the Finals.

About only way for the Driver tube plate circuit to hurt the Finals would be for both inter-stage caps (blocking and coupling) to go leaky and that just doesnt happen unlike some rigs that only use one coupling cap and the control grids see plate voltage. As you know they wouldnt like that! I have never seen it in a KW hybrid.

Terry K9TW

Thanks for the info on the radio. Shotgun the cap, Maybe but why change out just a couple and have the few more cause trouble down the road later. While I am in there why not, given there age. Just my opinion.
This is the third 12by7a tube it has gone through so something is up. Mike you have a great information site and I will be watching all of the videos for sure. BTW one of the 10 ohm 1 watt resistors had a crack in it so that is why I changed both. What would happen if I set the bias to 50 ma or 55 ma, would that make any difference in the operation. I don't want to give the radio back to the owner and have the same problem.
Mike; You be I am going to measure the voltages. There must be a commonality to the issue. The radios I usually work on are from the 20s and 30s and you be the caps get changed or face the smoke genie coming out of the box.

Because they're unlikely to be faulty. In close to 30 years of working on all sorts of electronic equipment I've changed maybe half a dozen genuinely faulty electrolytics. I know it's currently fashionable to go "OMG ZOMG MUST RECAP BECAUSE ELECTROLYTICS ZOMG" but they just plain do not fail that often.

Cheap shitty switched-mode PSUs are another matter. Poorly-specified capacitors with high ESR will fail when exposed to the stresses in poorly-designed SMPSUs. Guess what? Your Trio hybrid does not have a switched-mode PSU of any sort, never mind a cheap shitty one. There are very few aspects of these old rigs that could be described as cheap and shitty.

The more you fiddle about with the guts of a piece of equipment, the more likely it is you'll do more harm than good. I've had to scrap a couple of lovely old synthesizers (of the music rather than RF variety) because they've been "recapped" and then brought along to me to get fixed because they've just not run right since. Once they've been chopped about like that, there's no telling what mayhem has been caused elsewhere.

Quick question - was it cooking the driver valve *before* you "recapped" it? Was it misbehaving in any other way? Bet you wish you'd left it alone...

Concur, please clean up a bit guys.

You wouldn't talk like this on the air, would you?

I use this list for a reference for my 4-H group. (It is forming slowly, we'll see how well it does and how many kids sign on once school starts!)

I can't use the list for that purpose if I can't be sure there won't be a load of S- this and F- that in there. Please, consider this for a moment.

I'd be much obliged if y'all would tidy up the vocabulary -just- a bit, ok??

To all members,

Swearing on this group, in any form, will NOT be tolerated!! Swearing and using curse words may be accepted on other groups/forums, regardless how slight those words may be, but NOT on this group!! This includes modifying a word using characters such as "$" as a substitute for "S", abbreviations of swear words such as using the first letter of each swear word, and any/all other forms of swearing. If you can't respond without swearing then don't respond at all, it's that simple!!

49210. Adding Message Signature

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-06 14:59:23 UTC
From: Mike W5RKL
Topic: 49210 Message: 49210

To ALL members!!

There still appears to be some members, for what ever reason, who still don't get or have not gotten the message about adding a message signature at the end of their messages!! This is NOT because they were not told!!

Every person who applies for membership to this group and their applications is approved, that person is sent a couple of messages to the e-mail address they provided in their application for membership, that states this group's policies and rules. Therefore, there is absolutely no excuse for any approved member to not know what the group's policies and rules are!!

It takes less than 5 seconds to add a message signature to a member's messages before the message is sent!!

We have also informed everyone who uses an e-mail client software package such as Thunderbird, that the user can create a message signature that will automatically be applied to the message they send. All that's required is to edit the "Account Settings" and indicate the message signature you would like.

Message signature cannot be "screen names" used on other website such as "Gigawatt243" or "Ibeaham" or even an "email addresses" that contain your name. An acceptable message signature is as follows:

1. Licensed hams:
your first name followed by your ham call sign or if you don't care to use your call then just your first name

2. Non-licensed hams
your first name

Wow I must have not explained myself enough to the group. Here I go again so there will be some understanding.
The radio was recapped due to the main smoothing caps. One was open and the other was way out of spec. As I looked the radio over with a fine tooth comb and magnifying glasses I had found about 8 small electrolytic cap in various places on the pc cards had bulged out to the point of losing the rubber seal on the bottom. This was clearly seen and the caps were removed, tested and replaced. Since I was into the radio, all high voltage cap were replaced. Time, voltage, temp all play a factor in my decision on the replacement. I have had to many times where I had only replaced the bad caps in the high voltage areas, power supplies, and the equipment came back and I had to replace all of the rest of the caps. When it comes to a 2 dollar cap verse a
20 dollar tube or a 100 dollar transformer I tend to err on the side of caution. Sorry for the confusion. The radio is back on the air and this is what I had found and I could be wrong. The 12by7a tube was totally flat and one 6146b was flat. The two cathode resistors were replaced because of a crack in one of them so the two were replaced. Installed two new RCA 6146b tubes and the driver. I did check all of the voltages at the driver tube and all is good. I did check the setting for the bias and it was set to 150 ma. I set this back to 60 ma and tuned up the radio on 21.300. Set up my scope and neutralized the finals. The radio seems to be doing ok now. The owner turns on the radio and leaved it on for months at a time and I don’t think he checks the settings or retunes the radio. If anyone has any other ideas I am all ears but do keep the comments civil.

A question for the group?
Does the TS 530S need to have the remote plug like the 520,520s etc. The manual is not clear.It shows the external VFO line and the remote output going to an amplifier.

Thanks

Vic,

No, there's no requirement for a jumper or jumper plug being plugged into the TS-530 and TS-830 Remote VFO socket if the either one of the Remote VFOs, VFO-230 or VFO-240, are not plugged into the rear panel's remote VFO socket. The TS-530 and TS-830 Remote VFO DIN socket has an embedded micro switch that performs the same function as the TS-520 and TS-820 jumper plug or jumper wire between pins 8 and 9 on the rear panel's 9 pin VFO socket.

Hi Terry,

Thanks for the reply, I think it was right on. The resistors were way off with one being close to 2Meg, and the other 44K. I am now getting a defined DIP, as I would expect. I had thought that I use to get a DIP back when I first bought the rig used, and when I tune up my DX-100 it also gives a nice DIP.

While it was taken apart, I went ahead and risked really messing it up, cleaned the wipers in the VFO.

Cleaned up the PA Cage, and put in Ken's cage kit, has been sitting in a drawer for at least the last 5 years, and the caps did have the dark brown overheated look.

I did notice the top of the first 6146W looking from the front of the radio had some carbon like residue on the plate contact while I was cleaning it up. have never heard any arcing during my use with it, did notice the cap fit over the tube slightly loose, so with some slight bending of the wire it now sits better.

Loaded up in the dummy load fine, acted like it should, and with my old non-calibrated HM-102 meter it said it was at 80Watts on 20mtr. in CW.

Thanks again, love this group!

James WS4JH

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote :

"1. Plate Tuning Fail - Low needle reading, no dip"

"2. Plate and Load Tune - Low needle reading no reaction"

1. Are you saying after peaking the Drive in Tune mode you cannot get the initial plate current dip in Tune mode? If so, where do you have the Plate Load cap set at? Set it so the plates are closed ie fully meshed. This will give you the most discernable Ip dip to adjust the Tank to resonance. If you get no Ip dip then try it in CW mode. Dont leave it key down very long. You may have a problem with the Screen Grid voltage divider resistors.

2, Are you saying with radio in CW mode and panel meter in RF position when you flip to Send and alternately adjust the Plate Load and Plate Tune caps you get no or very low peak in RF relative power? If so, perhaps someone adjusted the RF voltage sensitivity pot accessed thru the side panel. Try adjusting the sensitivity pot for more deflection. 2/3 to 3/4 deflection is good spot to work with.

If you can load the rig in CW mode then will need to measure R5 and R6 56k ohm resistors on the HV Unit board. If one is bad replace both.

Vic,

The 530s and 830s do not require the octal plug you are referring to, they will operate perfectly fine without. However, during routine yearly maintenance, it is recommended to apply a small amount of deOxit to the socket and insert the male connector several times, this is mainly due to the miniature switch that is encased in the female socket and sometimes sticks etc. Remember to blow out socket.

49219. Hybrid Net Update (July 6, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-07 12:29:06 UTC
From: Mark Gilger
Topic: 49219 Message: 49219

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

There was no Saturday net.

The Sunday net was run by me, WB0IQK. There were 14 stations checking in under good band conditions. We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-511
0 running 599 twins

The reset were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a

very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 80, Sunday☐s total = 85
March 2014, Saturday☐s net total = 82, Sunday☐s total = 73
April 2014, Saturday☐s net total = 64, Sunday☐s total =43
May 2014, Saturday☐s net total = 66, Sunday☐s total = 35
June 2014, Saturday☐s net total = 43, Sunday☐s total = 59
July 2014, Saturday☐s net total = 0, Sunday☐s total = 14 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

49220. Help - 830S Frequency Display constantly counting up

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-07 00:10:28 UTC
From: n612dw@...
Topic: 49220 Message: 49220

oh great Obeewahnkenobees of 830 omniscience,

TS830 that has been running fine, EXCEPT now the frequency display constantly counts up from 1 to 99 mhz (all display digits counting up fine).

probably no coincidence as i just installed a 8mhz cw filter, i suspect that a connection between IF an freq counter board got compromised from my having to remove the board and solder in the filter ?

frequency is totally stable, no problem there, so must be localized to the display input? almost like the counter is not getting any input???

suggestions before i open it up and start chasing the schematic?

-bob, W9ZV

49221. Chinese microphone

Topic: 49221 Message: 49221

I brought one of those Chinese microphones listed as for TS820, 520 etc and suprise it don't work so I notified the seller and they sent another one. Suprise it don't work either. Putting an ohms meter on 20k my MC50 reads 1.2 on the insert side at the plug and on the Chinese ones read 9.5. They wont even work on my TS 680S. So I'm going to make a patch lead to use my MC60 until I can find an original one for my TS 520SE.
Just thought I'de let people know if they were thinking of buying one DON'T.
One question, will the 520 take to using the mic pre-amp on the MC60 mic or leave it turned off?

Robert,
Yes I agree with you if you have found a few of the Caps damamged then best to replace the rest rather than just one or 2. Like you say the problems that you get with Old Electrolytics is the Electrolite in them can dry and become in effective.

Also Like you say Time, Operating Temp and AGE are not good freinds of Electrolytic Capacitors, and for the sake of few mins and a few Pennies or Cents then save problems.

Cheers,

Terry G0TKJ

Ok-Glad that replacing Tune SG divider resistors fixed it.

Another common one is the SG divider resistors for the Driver Tube.

Unfortunately I am starting to see more and more carbon resistors going very high or open. There are times when the 300 supply bleeder is open and that can get you a nasty shock.

It wont be too long before someone is selling a total carbon resistor replacement kit!

Robert and Terry (G0TKJ),

I don't think you guys are aware of how sensitive the PC board foil runs and solder pads are in the Kenwood Hybrids. It doesn't take much heat to damage the foil run. While you may think the solder connection is fine, heat can easily damage the foil/solder pads even around the component lead that you can't see with the naked eye. I've seen damage to the foil runs occur at the plug pins that can't be seen with a high intensity light and a magnifying glass. The only way to find the cracks is to use an ohm meter. These cracks were created by simply replacing a component. The crack occurred at the component lead solder pad using less than 30 watts of heat. Therefore, the less stress you place on the PC board foil runs the better. This is not to say you should not replace a known bad component. All we are saying is to use some common sense and not replace components that have not be found to have failed.

Also, using the "shot gun" component replacement method may fix a problem in your radio but you will never know which component actually fixed the problem therefore you did not learn anything.

Bob

I doubt you did anything to the counter display board by installing a filter on the IF board.

You can make sure you have 1khz input from PLL board to the Counter Display board, but my guess is you have lost Q3 SN74LS00N. You may be able to confirm that by comparing output signals with O-scope at pins 6 and 8.

Can replace it with most any Quad 2-Input NAND gate chip. I replace them from time to time with a HD74LS00P.

Have to exercise caution with unsolder and resolder as easy to lift a foil. I use Hakko 808, but it can be done with solder wick.

You may be better off buying a Counter Unit from Bob Mansker. I suspect around $75.00. If planning to keep the radio this may be better option as you will have spare chips and spare display which is no longer available.

Mike: I agree with you 100%. The combination of heat and age can be lethal to pc boards, wiring, components, connectors, etc. This is most dramatically seen in rigs like the Heath "HW" and similar series, where there are multiple tubes and heat generating resistors in close proximity to the PCB. Also used to see this a lot in a certain generation of TV's with similarly bad results, but I don't think too many of those are still being worked on !

Robert , the last few lines in your last post say it all. Sounds like the actual owner/operator has no Idea how to use a hybrid radio.
You should urge him to trade his Hybrid and a few more bucks for a solid state radio where he will not be able to damage it by neglecting to tune up correctly.

No Bob, you're right, not many older TVs left.

I mean no disrespect towards anyone.

There are a lot of older point to point wiring and PC board ham gear still running strong that have vacuum tube as well as solid state device using multi-capacitor cans, some oil filled caps in older vacuum tube gear, and multi-capacitor multi-lead radial lead caps still around. The Heathkit SB-300 receiver has a multi-capacitor can electrolytic plus some axial lead electrolytic caps below the chassis.

The quality of electrolytic capacitors have improved significantly over the years. A 20ufd 450VDC electrolytic capacitor made in the 50s does not have the same quality as a 22ufd 450VDC electrolytic capacitor today, the materials and manufacturing processes are much better today than back in the 50s. I use to own a Kenwood TS-820S and the HV caps, both 100ufd 500VDC, had "dimples" on the vent side (lead side). It was obvious the caps had been stressed beyond their normal operating range by some previous owner. I replaced them after 6 months owning the 820 with new caps. I have a Heathkit SB-303 all solid state ham band receiver. When I bought the receiver I pulled the power supply filter board. The main 2000ufd 40VDC filter capacitor (I think I have that cap value right) had a pressure relief value breakage allowing the capacitor to leak onto the positive end, nothing leaked onto the board itself. I replaced the cap and perform an alignment check, the +15VDC was off a little but other than that bad cap, the receiver worked fine and still does. That receiver was marketed in the 70s which would make it approximately 39 years old now and the original capacitors are doing fine due to the quality of the caps were significantly better than the caps of the mid 50s.

There is the mentality that it's good insurance for the future to replace old components without testing them to determine if they actually need replacing. I'm sure there are some who will replace all the old electrolytic capacitors then say they notice a significant difference in how the equipment operated. The problem with that statement is, what are they using to compare the result with? Did they perform test and measurements and made notes "before" the capacitors were replaced then perform the same test and measurements "after" the capacitors were replaced so they actually have some figures to compare? I doubt most people do that.

Well, the PC lands are sensitive, I admit, and I have damaged some using
solder wick & my Weller soldering iron. But since I have acquired my new
Hakko de-soldering iron, I feel very confident replacing components on
my Kenwood PC boards. I highly recommend you guys consider buying one,
it is wonderful. The components just fall off the board.
I purchased mine from MCM electronics, and I think they still have them
on sale too.

Re microphones. Carefully check out the connections to the 4 pin mic connector.
But, be warned, not all 820S are the same. Mine uses a different connection system than that in the manual.
They work best with medium to high impedance mics. Say 600 Ohms and up.
Lo Z mics seem to have too low an output to drive the TS820 series. I use an electret mic with a battery powered preamp, controlled by a PTT switch. Works fine, tho I am basically more a CW person.

Good day all and I hope your Monday was a good one. Mike, yes I do understand the foil tabs are sensitive to be sure. I did but a quality soldering station with temp control. I do a lot of repairs so I want a good one. I never do any close work without wearing my magnifying glasses and yep my wife thinks I look like a man from outer space and the fact I am getting long in the tooth. If you overheat the pads the glue that holds the foil on will give way and then you have a mess. Heathkit was good for that. Now this project is off the bench the next one is a Hickok 752 tube tester I picked up for 20 dollars. A good cleaning with a couple of cans of deoxit should work.
Robert.

hi terry, i dont think i did anything to the counter board itself (as i said it worked just fine before i started fiddling).

i suspect i just have an intermittent inter-board connection between them somewhere. That may have been caused by my diddling around.

I did see the 1khz input at Q3 - the old 74xx TTL logic is kinda tough and to break and is very tolerant.

and as i sit here I noticed that it just fixed itself... so its an intermittent somewhere.

i do plan on keeping the radio as its a very cherry example and i just acquired it a month ago or so.

who or what is a Bob Mansker?

Hi Terry,

pretty close call... the output of the /2 flip-flop circuit created by Q3a and Q3b is stopping, but the input (coming from Q6 pin 14) is always fine.

if i put a few drops of freeze spray on either C21/22 or R34/35 or even the 74LS00 NAND gate, it corrects itself and begins to work. This lasts until it warms back up again. But im not convinced its the 7400 as these LS ttl devices are rather bulletproof. They either work or dont work.

but this seem like it might be somewhat of a design flaw, as the circuit seem to violate the TI specs for the 'LS00 gate for maximum allowable voltage for a valid input low signal (ViL). The TI specs sez that maximum allowable input voltage for ViL is .8v. Yet the input voltage is always above 1volt for either pins 10 or 4 of Q3. Freezing the parts is probably marginally just causing it to hit the threshold or catching things on the edges. I have a 350mhz scope on it maybe its just the edges that i cant see?

I cant really visibly measure the difference/change with the O'scope but at these edges of the spec, weird things happen and its hard to predict.

it looks like removing the counter board is going to be a major PITA that i dont want to undertake unless i absolutely have to (i dont even see how to remove it without the whole front panel coming off).

what are they gaming with the 47k and 5pf caps for on Q3 pins4/10 ??? I guess i dont underferstand the circuit, can you provide some guidance?

-bob

Bob,

The counter board, X54-1540-00, is easily removed. With top cover removed...look for the 2 small "allen screws" at the front-top of the unit...there are two more screws at the rear or the board..on the left and right corners

I tried to steer you toward the common problem with counting up. I didnt see anyone else respond to you. Some other KW repair men with TTL knowledge and experience have surely seen this problem and can help you.

You may be correct that it is a bad solder connection. In my experience it has not been at the Molex connector.

All I can tell you is that I have changed half a dozen of the NAND gate chips to fix this problem in TS530/TS830 rigs. Never changed any associated discrete components. Maybe it was cold solder joint and not a bad chip and the change out resulted in fixing the solder connection? I dont know. I do know that this Counter unit unlike the TS820S is not known for bad solder connections.

I am not a TTL guy, just a KW repair man. Too old to learn ancient digital logic!

Have fun

Topic: 49240 Message: 49240

Hello all. New to the group. I just acquired a TS-830S and all is well except for the loss of PLL lock at the upper & lower band limits of the 14 and 18 MHz bands. In both bands I suddenly lose all voltage at PLL TP1 when I get within approx. 90khz of the upper & lower band edges. Adjusting T3 & T4 on PLL has no effect on this problem and when set as per step 9 of service manual to its proper voltage the problem persists. All other bands work perfectly. In fact these two bands work perfectly except I can't tune in the edges without losing display, xmitt & rcv (PLL Lock). Looking at the VCO signal at D40 is the same. Suddenly drops out when band edges are reached. Not real familiar with this rig and very limited test equipment. Any thoughts are appreciated.

Well, I've repaired a few of the 830 display boards, and it has always been poor soldered joints that have been the problem. There are a lot of through hole connectors joining tracks on both sides of the board, and these can be the culprit. I usually solder a wire through them to each side of the board. Where the connectors go on the board can be troublesome as well, sometimes they are loose with a cracked track near one of the pins. It is usually, just a question of re-soldering and cleaning contacts, and in the end you fix it.

Steve:

Do you have a means of measuring RF voltage ie a RF probe and VTVM or O-scope? Do you have a Freq Counter? Hard to troubleshoot PLL without basic test gear.

Someone may have messed with the BPF-B adjustments (T7, T8, T9).

You can carefully get on the Emitter of Q35 (I use micro-grabber test lead but may be able to use straight pin or floral pin) and look at the RF voltage level. Should be approx 100mv to 150 mv at Fc.

Best to substitute a RF sig gen signal in lieu of the VFO signal, but you can roughly check the BPF alignment by monitoring the RF voltage at Q35 emitter and slowly rotating the VFO knob to see the peak in voltage. Problem is with the VFO gear reduction not as easy to see a precise peak. It makes it too broad. Worth a try to see if the peak is grossly off. Peak should be at 24.580mhz which is 14.580mhz which is approx 5.750mhz VFO input to the PLL board.

If you have a good RF sig gen then unplug VFO from Conn 5 and inject 5.750mhz @ 200mv test signal here. Now can swing the RF sig gen frequency to see a definite peak in RF output voltage at Q35. Not to uncommon to find it shifted slightly high or low but not grossly off.

Absent necessary test gear you could note the position of T17 and try adjusting it for max rf voltage at emitter of Q35. I would not try adjusting T7,T8, T9 without a Sweep Gen. Only make things worse.

If all else fails buy a good replacement PLL board from Bob Mansker and swap them out.

So you are saying that you are familiar with the TS530/TS830 repeating 1 thru 99 count problem and you routinely fix it by reheating solder joints or installing wires in vias.

Please share where you apply the heat and wire jumpers so Bob can fix his problem. Also where are the contacts on the Counter board that you clean?

I want to add this to my notes as I have been apparently throwing away good NAND gate chips to fix this common problem!

Hello Terry
Ok, this one is beyond my meager test bench. I have a rf voltmeter but not calibrated and only use to peak coils and such. Have a digital rigol oscope (100mhz) which I can try but not exactly high end. Bob just shipped me a PLL. What are the chances this will just drop in and work without alignment?? thanks so much for the quick reply

I did not say I had repaired a board with this particular problem, but I've had boards where the display stops with fixed digits, blanked out displays and boards that ceased to work after a short time. In every case it was a soldering problem, where repairing the poor "vias", and going over the many soldered joints eventually cleared the problem.

Pushing on & pulling off the connector plugs eventually cracks the tracks around the pins. Some of the PCB tracks go UNDER the connectors and I have had to hard wire those. Yes - you can try and narrow down the fault by scoping at the chip pins, but in some areas of the display board because of the high component density, this is not easy.

OK I clearly misunderstood you .

This thread was about a TS-830 display that runs from 1 to 99 and repeats over and over. I thought you had first hand knowledge that re-soldering and installing wires in specific vias resolved this problem. I agree if it is intermittent then not likely the chip, but in my experience it commonly happens every time the radio is powered on. This why it led me to look at the waveforms on this chip.

It is very interesting that there is virtually nothing in the literature that would lead us to believe that the TS530/830 Counter unit suffers the same malaise as the DG-1. I wonder why that would be the case? Perhaps I have missed the discussions? Pretty hard to miss them for the DG-1.

Cracks at the Molex pin pad to pc trace interface is well known and discussed on this forum many times. It is most common on the IF board that is pulled very frequently. Very seldom see it on the Counter Unit board in my experience. These cracks are hard to see due to the solder mask and can cause intermittents. However, any connector body motion should be an indicator of potential trouble and should be examined under magnification and good lite.

This is why I always caution new folks not to routinely pull molex connectors and clean them as so many advise. Very easy to pull connector body off the boards and to induce a latent failure. Any side to side rocking motion can induce the cracking that you describe.

I always check all Molex connectors and any that have any motion are suspect.

I didnt realize you were talking in generalities. I was really hoping that you could point us to the fix for the problem that the thread was discussing. If I have been needlessly replacing good NAND gates I want to know about it.

The problem with reheating all solder connections and cleaning all molex connectors and cleaning all relay contacts is this:

1. You have no idea what fixed the problem if it infact does.
2. You have jeopardy of breaking something (ie immediate failure)
3. You have jeopardy of inducing a latent failure that will manifest itself down the road

As Mike W5RKL so correctly points out you have to be very careful un-soldering and re-soldering these old phenolic boards.

I dont have any pc trace to pin pad or other jumper wire "repairs" on any of my rigs boards and dont do it to customers boards unless they authorize it. Just my preference.

Sorry I misunderstood what you were saying. I was anxious to talk to someone who had seen this problem before and understood the root cause and had the fix. As I said I have been replacing the NAND gates which fixes the problem, but it may be bad solder connection ? I look at all 14 pins under magnification and havent noticed any that look suspect on Q3.

Maybe Bob will be able to tell us for certain?

Terry K9TW

Steve:

I depends on your definition of alignment.

Most will work pretty well as this board typically has the least amount of golden screwdrivers applied to it other than Carrier Osc trimmer cap adjustment which has a bit of personal preference to it (bass or treble audio response).

I would put it in and power rig and see how it works, but I would then refer to the service manual and check following:

1. Adjust Carrier Osc level
2. Adjust LSB/USB Carrier Osc trimmer caps (better way is to inject audio in mic line and adjust 3dB roll off on external wattmeter. Absent that test gear can use the Marker/S-meter/Zero Beat method described in the Survival Guide in the maintenance section to get close).
2. Step 9 VCO adjustment (at least with with a DMM)

If you are going to work on these rigs suggest you buy a Freq Counter when you can.

You should be able to compare your RF probe and VTVM with your Rigol. Rigol scope will be fine for this work.

Interesting thread.

I too do not condone messing with pulling connectors and such as i dont want to cause "maintenance induced failures" from these older rigs. I may try to touch up the connections to Q3 from the top of the board as I dont want to disturb it unless needed.

i didnt see any responses to my question regarding the design and the violation of the Valid_Input_Low voltage for the LS7400 spec seen at the NAND gates. replacing it with another 7400 MAY fix it, but not because its broken, but because another chip may work because of tolerance to the violation.

Any thoughts regarding the design (read my prior post) ? What is the purpose of the 47k resistors and being capacitor coupled inputs for DC ttl inputs on Q3 pins 4&10 ?

tnx Joe/Terry/Stephen.

Interesting problem. If you don't mind I would like to throw my 2 cents in.

Having designed a few frequency counters I have some experience with using 74ls00 as a gate control. I think your assesment of the chip being on the edge is correct. Where I found the 74ls chips to be marginal I insured that the bypass cap on the +5v was close(r) to the chip and that the power supply was "stable". Check for ringing on the 5V line. Oviously check the voltage regulator. Also verify there is a good ground (0v) connection on pin 7 of the 74ls00, and on the chip that is supplying the +1V ViL input.
If you have already done that, sorry, just ignore my rambling.

My experience with the DG-1 is that it typically was a ground plane conneciton that needed re-soldering. I know you don't have a DG-1, but my theory is that KW had issues with wave soldering and the gound plane was sore spot.

Steve:

The XG-3 would be more useful if it had sync capability. You would also need another RF sig gen to inject the marker frequencies.

You can use the XG-3 and your O-scope or RF probe and meter to sweep the BPF using the old fashioned manual method. A little tedious but will result in accurate display of the frequency response as it currently sits. Not a good method for trying to make adjustments.

Connect your Scope or RF meter to emitter of Q35. Unplug the VFO input and substitute your XG-3. Set for 0dBm output level. Now step thru at approx 100khz steps from 5.000mhz to 6.600mhz and note and record the RF voltage level at each frequency step. As you get closer to Fc use smaller steps. The more steps you record the more accurate will be the results.

Now make a graph of the RF voltage vs the Frequency. Voltage on the Y-axis and Freq on the X-axis. You are now looking at the As-Found frequency response of the BPF. Can hand plot on graph paper or use Excel to produce a nice graph.

I can email you sample TS-830 graphs of how I use to do this before I got a Sweep Gen and now using a Spectrum Analyzer with Tracking gen.

Steve:

I forgot I have posted on my website a copy of the manual sweep method of TS-830 BPF. Go to k9tw.com and look under Photos/Videos tab.

I posted this as someone else had contacted me off the Reflector asking about how they could see where the BPFs currently sit. Same method can be employed for each filter. Have to follow the steps in the Service manual to get the respective filter switching diodes turned on and to determine where to connect your XG-3.

Steps could use some more meat on the bones so if you get confused contact me off list and I can help you.

The graph you see posted was produced with a regular RF sig gen and a RF millivolt meter. As noted you can use your XG-3 and either O-scope or RF probe and VTVM. You dont care about accuracy of measured RF voltage at emitter of Q35, but you do need accurate frequency input from whatever RF sig gen you use.

Greetings from sometimes sunny Pitt Meadows, British Columbia!

I'm a brand new Amateur Radio operator and I've just recently become the proud owner of a TS-520. Even more recently, I worked a few stations all the way east of the continent with the help of my home-brewed wire dipole. I'm pretty pleased with what I've done so far, considering I'm totally new to this, but of course, would like to learn more about the intricacies of the radio that I use.

So let's start at the beginning, the tuning process. When I got the radio, I inherited a laminated card with the tuning instructions. I thought I'd post it here to get some opinions on it and hopefully understand it better:

1. PLATE IDLING CURRENT
Meter in IP, Mode SSB, flip send and meter should hit 60 mA.If not, adjust BIAS on side panel.

2. DRIVE
Meter in ALC, Mode TUNE, flip send and adjust DRIVE to MAX ALC. If not ALC is indicated, increase CAR control until there is a reading.

3. PLATE TUNING
Meter in IP, Mode TUNE, flip send and adjust PLATE dial to see meter DIP, leave in DIP.

4. PLATE and LOAD TUNING - Full power adjustment
Meter in RF, Mode CW, flip send and adjust PLATE dial to MAX meter and then LOAD dial to MAX meter. Use RF VOLTS on side to adjust to give 2/3rs meter scale.

5. PTT Operation
Meter in ALC, Mode SSB, key Mic and talk into Mic. Adjust Mic gain until meter peaks to within top limits of ALC. Do not overdrive Mic.

6. VOX Operation
Key up and talk again, adjust VOX GAIN CONTROL on left side panel until VOX relay just operates.

I also watched the video by W2AEW and pored over the excellent instructions from K4EAA. Neither of these make mention to the adjustment of the BIAS or RF VOLTS on the side panel. I do, as a matter of course adjust the bias to 60 mA religiously, and the RF VOLTS gave me quite the scare when I discovered my ham fisted adjustment could make the meter peg out so easily!

What exactly do these adjustments do?

Another thing that took awhile for me to figure out was why I could not zero the meter! It was always hovering around the 40-50 mA mark! For the longest time, I thought I broke the meter, or worse, the radio, and was trying to figure out if there was a screw I could adjust to zero the meter. Much poring over the manual later....I found that the RF control MUST be set to MAX in order for the meter to be zero.Oh well, chalk it up to another newbie

mistake. Which got me to thinking...what else am I doing that's wrong?

And so I find myself here.Thanks for taking the time to read.

73,
Mark VA7PWK

Bob

As I mentioned I am not a TTL logic guy. Last frequency counter I built was in the 70s! The chips of that day were 7490/7475 and I used RCA Numitrons for display and they looked great but caused my electric meter to spin off the house!

If I had to hazard a guess three configs come to mind:
1. A Flip Flop with the 47k resistor providing the feedback from the Not-Q output back to the input to give the precise divide by two? I have measured the input and output and it is precisely 10hz in and 5hz out just as noted on the schematic.

2. A Schmitt Trigger Oscillator with the 47k resistors and 5pf caps determining the operating frequency? I dont think so as RC time constant doesnt look correct?

3. The 5pf caps and 47K resistors just form a simple RC Differentiator to waveshape the rectangular pulses from output of Q6. Look at waveshape at Q6 Pin 14 and then look at waveshape at Q3 Pins 4 or 10.

There has to be some digital logic guys among the members who can tell us how this circuit is configured.

KW engineers didnt always follow the "rules". They did however copy a lot of good and proven design. I always like to give them the benefit of the doubt.

Time for me to move on.

I have been modifying Phone Patches to serve as Digital Interfaces.

I do have a Kenwood PC-1A (8 pin connecter) to use with a Kenwood 2M FM system.

But I also want a digital interface for my TS-520. I could buy a PC-1 (4 pin connector) and modify it.

The TS-520 does not have phone patch inputs. The later versions of the TS-520 (SE) do have direct phone patch inputs.

I have not looked at the circuit details of these inputs.

Is there a reson I should not modify my TS-520 to add the phone patch inputs like the TS-520SE has.

Are the PCBs interchangable between versions of the TS-520.

I have also considered adding the ouputs for a DG-5.

Hi Bob,

The cross-coupled outputs of the NAND gates make an RS latch.
If we call pin 8 the Q output then pin 6 is the Q/ output, pin 10 is the SET/ input, and pin 4 is the RESET/ input.

The purpose of the caps is to allow the edge of the input signal to produce a pulse at each input to the RS latch. If the caps are discharged then bringing the input signal from Q6 low will pull both the SET/ and RESET/ inputs low. The caps will charge up from the current from the TTL input pins and also from current through the 47K resistors. Normally driving both the SET/ and RESET/ inputs low will result in a undefined state. What makes this work is that C5 and R8 prevent the Q/ output from changing at the same time as the Q output.

The service manual, in the counter block diagram, defines this as a divide-by-two circuit. I can't find my copy of Don Lancaster's TTL Cookbook to see if something like this was included in his book but it wouldn't surprise me if it was.

I don't know if this helps.

Interesting thread.

I too do not condone messing with
pulling connectors and such as i dont want to cause
"maintenance induced failures" from these older
rigs. I may try to touch up the connections to Q3 from the
top of the board as I dont want to disturb it unless
needed.
i didnt see any responses to my
question regarding the design and the violation of the
Valid_Input_Low voltage for the LS7400 spec seen at the NAND
gates. replacing it with another 7400 MAY fix it, but not
because its broken, but because another chip may work
because of tolerance to the violation.

Any thoughts regarding the design
(read my prior post) ? What is the purpose of the 47k
resistors and being capacitor coupled inputs for DC ttl
inputs on Q3 pins 4&10 ?
tnx
Joe/Terry/Stephen.

tnx for the input (Terry/Bill/Steve).

the pair of NAND gates does indeed provide the classical RS Flip-Flop divide by two circuit. That part of it is straightforward and understood.

the piece i dont underferstand is the 47k and AC input coupling caps (C21/22) on Q3A and B. With only 5pf caps, not much of an RC is created - so i can only think of it working on the edge transitions. Maybe to produce a pulse on the latch?

when the circuit is running correctly, i do indeed see a good output waveform on Q3 pins 6/9. When it isnt working, I see what appears to me to be an invalid input voltage violation on Pins 4 and 10 - its not going low enough to be seen as a valid logical low. Its only going to about 1.2 volts - not enough to meet the 74LS00 spec for ViL of .8v max.

All this aside I went ahead and decided to touch up the pins on Q3 and the caps C21/22 (because some freeze spray made it work), suggesting a faulty connection. Put some clean solder and a smidge of flux on Q3 pins and caps, and a couple of related nearby vias to re-flow them.

Today it's been working all day without issue - all seems well.

I can only think it was something related to the integrity of the connections but they visibly looked fine even under a magnifier and good light (and from the bottom of the board as well). Still dont understand the ViL violation and how they depend on it working, and what the 47k and 5pf caps serve.

i guess i cant argue with success.

Thanks for all the help guys. I hope this stays as a stable fix.

Hi Bill,

just read your explanation - this is exactly what i was looking for. Thanks.

the RS FF (creating a f/2) is straightforward but the AC coupling and 47k's had me thinking. Hadnt thought of the R8/C5 effects... DoHHH !

the RC has to only delay by about 11-15ns on an LSxx family part to be seen as valid on the inputs to prevent the undefined state.

makes sense, tu

been a few years since i stopped designing this stuff !!

Don Lancaster's cookbook - man, i think i even have that somewhere along with the other TI hardcover data books on this TTL logic.... small world

Topic: 49263 Message: 49263
Attachments: 1 described; binary payloads are missing from this source WARC

I sent this last week and based on non response, wonder if it went through.

==========

Hello:

I'm new here. I have a TS-520SE which works fine except... Lately, intermittently, the S meter travels all over the place, sometimes pegged. The receiver still works but I think sensitivity is less during these events. I tried aligning the receiver as described in the manual but could not locate all of the adjustments on the IF board.

I have the operator and the service manual and neither shows the physical layout of parts. So I adjusted what I could find. Any help gladly accepted.

49264. TS830S No RF output

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-10 00:51:47 UTC
From: allen3500@...
Topic: 49264 Message: 49264

I am having a Senior moment here. I cannot, for the life of me, located the place where I'm losing Drive in this TS830S.
I know it's right in front of me, but---

I am using another TS830S as a receiver on the bench and both are connected to dummy loads.
I can observe S meter deflection, on the receiving radio, upwards of half scale when tuning the 830 in question.
I can hear audio being transmitted when speaking into a Mic, but NO ALC indication, and No RF output on the wattmeter or RF indication on the radio's meter.
I do have 60ma of BIAS indicated as well as measured at the finals, but NO plate current reading when tuning. Other than the 60ma.

Here are the readings I am getting with all tubes in place:

12BY7A Driver

Receive Transmit
0VDC PIN1 4.23
-47.3 PIN2 +.447
0VDC PIN3 0VDC
0VDC PIN4 0VDC
12.6VAC PIN5 12.6VAC
0VDC PIN6 0VDC
337VDC PIN7 303VDC
247VDC PIN8 219VDC
0VDC PIN9 0VDC

6146B Finals

0VDC PIN1 0VDC
12.8VAC PIN2 12.7VAC
254VDC PIN3 238VDC
0VDC PIN4 0VDC
102.7 PIN5 -60
0VDC PIN6 0VDC
0VDC PIN7 0VDC
0VDC PIN8 0VDC
926VDC Plate 871VDC

I seem to be losing drive somewhere.
FYI - I have checked C1 on the Final board and replaced the cathode resistors account the old carbon ones were out of spec.
I have resoldered the tube socket connections on the RF Board, and checked the band switch.
Maybe C29 on the RF Board in bad?
I also replaced RY1 with one of Ken's new relay packages.

I know it's right in front of me, sooo--- what say you OH Great Sages of Kenwood land????
Thanks for the help!
Jim wb5twc

Jim:

Because you have 900vdc on the panel meter does not mean you have it on the final tube anodes.

Can you safely measure the 900vdc at the top of the plate choke in the PA cage?

If it is missing and the choke winding does not appear to be burned or discolored then suspect that the small VHF choke at a right angle at the base of the choke is open. Ken K4EAA includes one in his rebuild kit. While there look at the RF bypass capacitor and if it is discolored or cracked replace it.

Joe:

Did you try cleaning the RL-1 Aux relay contacts before messing with IF transformers?

The X-ray views of the PC boards in the Service manual shows location of all the components???

This doesnt sound like an alignment issue.

Are you trying to do the alignment noted in the Owners Operating manual maintenance section or the full alignment in the service manual? Need calibrated RF sig gen to do the full service manual alignment. Can use the Marker signal to do an abbreviated alignment that typically will put you in very good operational state unless there has been a golden screwdriver on the IF board.

I would clean the relay contacts first to make sure you arent losing AGC bus voltage.

Hi

I would have thought that the 5pF capacitors & 47K resistors (which form a CR time constant at about 1/4µS) are just edge triggering a set/reset flip flop, to act as a divide by 2 with both Q & /Q ouputs.
The arrangement is not particularly unusual using TTL type chips. The stages will be falling edge triggered.

Cheers
Graham

OK you are saying that you have good 900vdc at anodes of the tubes and you have good SG voltage and you have RF drive, but no RF relative power indication and no RF output on external wattmeter. Is this correct?

If you place the SG switch in off and in CW Mode and flip to Send with CAR level pot full CW can you peak the ALC indication? If so, you have good rf drive voltage swing at the 6146 control grids and proper operating bias voltage.

It would be rare to have a bad RF relative power diode and a bad TR relay contact at the same time. If bad TR relay contact or a bad solder connection at center of the SO-239 connector inside the PA cage (sometimes can pull the tinned bus lead from the connector) you should still have good RF relative power indication as pi-network will see the voltage divider as its load and develop high rf voltage across it.

Mark,

Welcome to the group and greetings from sometimes sunny Tacoma, WA. Towards the end of your post you asked: "what do these adjustments do?" Are your referring to Items 1 through 6, or the bias and RF Volt adjustment?

You do not have to adjust the bias every time you tune up or change bands. If you do, something is wrong! Once CORRECTLY set according to the "operators" or the "service manual," you should NOT have to mess with it again...unless you change final amplifier tube(s). It's good to CHECK it every once in awhile...to make sure all is well. The RF Volt adjustment gives only a RELATIVE indication of power output...you can not increase/decrease output by just turning up the indication to a higher value! It is a tuning aid only.!

There is a rather large amount of information contained in previous "conversations" regarding what various controls do. Go to this groups "HOME PAGE," and on the left side, under the picture of the really nice Kenwood station, click on "conversations," Enter your search criteria in the box at the top, click search group(s). Entering say: "6146 bias)...you may get hundreds of "conversations" mentioning it. Being specific helps. Also, you can check out the "FILES" section at the same home page...lots of good stuff there too.

Jim,

Based on the 6146 voltage indications, especially pins 1 and 5, here is what I think.

1. You said the IP meter indicates 60ma.
2. You said the voltage on the 6146 grids, pin 5 on both tubes, is -60VDC.

You cannot have 60ma of IP idling current in transmit if the 6146 cathode voltages (pin 1 on both 6146 final tubes) is 0VDC. You indicate the 6146 grid voltage is -60VDC which indicates the transmitter is keyed.

Having -60VDC on the 6146 final tubes pin 5, the 6146 grid, indicates the bias circuit is switching properly from standby to transmit. The typical 6146 grid voltage, in standby/receive, is approximately -101VDC.

I think you need to perform the final tube voltage measurements again in both transmit and receive.

Craig,

If you look at his screen voltage measurement, pin 3, he indicates the screen voltage is 235VDC which indicates the SG switch is in the ON position and the final amplifier is in transmit. IF the SG switch was in the "OFF" position then the voltage on pin 3, 6146 screen, would indicate approximately -100VDC. The normal standby screen voltage is approximately +255VDC to +260VDC. When the 6146 tubes begins to conduct the screen voltage decreases due to current flowing in the 6146 screen circuit which results in a voltage drop to occur in the 6146 screen circuit, hence a reduction in screen voltage.

Now the cathode voltage, 0VDC on pin 1, he indicates does not agree with current flowing in the 6146, that's why I asked him to measure the voltages again.

I have a video on my website that explains in detail how the TS-830 SG switch circuit works

http://w5rkl.com/wp-content/uploads/2014/03/Function-of-the-TS830-SG-switch.wmv

Topic: 49264 Message: 49279

By the way, the 6146 pin 1 (cathode), pin 4 (beam forming element) and pin 6 (other side of the cathode) are ALL connected together, "internally" in the 6146 tube AND connected together on the TS-520 point to point wiring and the TS-520S/TS-520SE, TS-820, TS-530, and TS-830 Final Unit PC boards.

I have a video on my website that explains how the 6146 beam forming element works and how it forms the electrons, as they flow from the cathode, into sheets of electrons focused at the plate. The video also show the schematic diagram of the 6146 tube and that the beam forming element, pin 4, is connected back to the cathode.

Pin 8 is connected to the metal band around the base of the 6146. Pin 8 is typically connected to ground so there will be no voltage on this pin.

Pin 2 and 7 are the filament connections. The KW hybrids have the 6146 filaments wired in "series" so pin 2 of V1, the front 6146, will have 12VAC and V1's pin 7 AND V2s pin 2 will have 6.3VAC. V2's pin 7 will be "grounded", completes the filament circuit, so it will have zero volts.

Good point, Mike. I think I wrote that at about 2 o'clock in the morning without thinking it through.

I had a fitful 530S last year that transmitted intermittently until I traced the fault to a glitchy SG switch. This became my knee jerk "go to" troubleshooting step, kinda like turning your computer off than back on :-)

OK you are saying that you have good 900vdc at anodes of the tubes and you have good SG voltage and you have RF drive, but no RF relative power indication and no RF output on external wattmeter. Is this correct?

Terry, I DO have good 900+ plate voltage at the anodes. I DO have good SG voltage, BUT I seem to be losing RF Drive somewhere.

If you place the SG switch in off and in CW Mode and flip to Send with CAR level pot full CW can you peak the ALC indication? If so, you have good rf drive voltage swing at the 6146 control grids and proper operating bias voltage.

I have NO ALC indication regardless of SG switch position. I DO have proper operating BIAS, measured a the 6146 sockets with tubes installed, BUT I seem to be losing the RF drive prior to reaching the 6146 control grid.

Unless I'm, losing my mind, I don't think I am getting any RF drive from the RF Board. I replaced the 12BY7A with a known good tube to no avail, and the voltage numbers at the tube seem to be acceptable.

Jim

Hi Mike!

You cannot have 60ma of IP idling current in transmit if the 6146 cathode voltages (pin 1 on both 6146 final tubes) is 0VDC. You indicate the 6146 grid voltage is -60VDC which indicates the transmitter is keyed.

I agree. As I indicated in my original posting, I have -102 in receive and -60 in transmit on pin#5 of both tubes.
It appears that the BIAS circuit is switching properly.
As you know, pins #1, #4, and #6 are all tied together.
I rechecked the voltages and I am seeing 0VDC in both receive and transmit.
I'm guessing that in transmit pin #1 should be a couple of volts DC? The zero voltage readings in transmit is what originally led me to believe that I had lost drive prior to reaching the 6146 finals, or am I way off base here?
What should I be seeing on pin #1 in transmit with drive and/or without drive?

Thanks for looking at this for me.
Maybe you and Terry can get me back on track.

Cheers!

Jim,

If the 6146 cathode circuit is open, which it appears to be especially since you indicate the 6146 pin 1 (cathode) voltage is 0VDC, it's impossible for the IP meter to indicate 60ma in TX.

Have you checked the final amplifier cathode resistors, there are 4 of them, 20 ohm 1/2 watt each. Connect your ohm meter's RED lead to pin 1 and the BLACK lead to the chassis, the ohm meter should show approximately 5 ohms. If the meter shows "infinity" then the cathode circuit is open which is why the cathode voltage in TX is 0VDC.

By the way, I forgot to mention before. If the 6146 cathode voltage IS actually 0VDC then the screen voltage will be closer to +255VDC instead of +235VDC and the HV measured at the 6146 plate caps will be closer to +920VDC.

I think you have final amplifier cathode circuit issues, not loss of RF drive in your 830. You need to check the 6146 cathode resistors to see what is going on there. Connect your ohm meter RED lead to pin 1 and BLACK lead to the chassis, the ohm meter should indicate approximately 5 ohms. If the ohm meter indicates "infinity" then the cathode circuit is OPEN which is why the cathode voltage in tX is 0VDC.

Guys, a watt meter or the SG switch, at the moment, has nothing to do with Jim's problem.

Jim clearly stated he has no plate current AND no ALC indication. He incorrectly stated he has "60ma bias". There is no such thing as 60ma of bias.

Jim also provided a list of 6146 receive and transmit voltages that he measured at the base of the 6146s. The voltages on the left are with the 830 in receive and the voltages on the right are with the 830 in transmit.

Look at the 6146 transmit "cathode voltage", pin 1, Jim says it is "0VDC". Couple that with Jim's statement that says there is no plate current and you would know there will be NO ALC, no screen current, and NO plate current in transmit!!

For now I believe Jim's problem is not a loss of RF drive from the driver but rather a failure in the TS-830's 6146 final amplifier cathode circuit. I base this on the 6146 cathode voltage of 0VDC in transmit AND Jim's "no plate current" comment.

Jim says he has 60ma of bias. There is no such thing as 60ma of bias. The "60ma' is current flowing in the 6146 between the cathode, screen, and plate. This is based on the bias voltage set by the bias pot.

Topic: 49264 Message: 49289

Jim,

I agree, the 6146 tube sockets AND 6146 tube pins 1, 4, and 6, are all tied together both internally in the tube itself AND by point to point wiring in the TS-520 6146 tube socket as well as the 6146 tube sockets mounted on the PC boards in the TS-520S, TS-520SE, TS-820, TS-820S, TS-530, and TS-830.

What's important is to understand why pin 4, the Beam Forming element, is tied back to the cathode and what affect that has on the overall operation in the 6146 Beam Power Tetrode. What does the Beam Forming element actually do and how does it accomplish its task? Below is a short explanation of what the Beam Forming element in the 6146 does. It's also covered in the tube manual as well as in John T. Fryes, "Basic Radio Course" book.

The Beam Forming element, pin 4, when connected back to the 6146's cathode, whether internal or external at the tube socket pins or pc board wiring, makes the Beam Forming element have the same potential as the cathode, negative in respects to the plate. As the electrons flow from the cathode towards the plate, some attach themselves and flow in the 6146 screen circuit while the rest continue on towards the plate. As they pass by the Beam Forming element, the negative potential of the Beam Forming element repels the electrons into "beams of electrons" focused directly at the plate. I have a video that explains how the beam forming element in the 6146 works. You can find it on my website at:

http://w5rkl.com/basic-electronic-videos-2/

Scroll down the page page and click on "The 6146 Beam Power Tube" video

I have a couple of RCA tube manuals that discuss, in detail, basic and advance vacuum tube theory as well as teach you how to interpret vacuum tube graphs. You can't proper service a vacuum tube circuit if you do not understand how vacuum tubes work and how the voltages affect the overall operation of the tube itself!

http://w5rkl.com/manuals-and-documents/

Scroll down the page to the listing titled

/*"Low and High power receive and transmit vacuum tube manuals and documents"*/

I recommend you download the tube manual and spend some time studying and learning how vacuum tubes works. You can't proper service a vacuum tube circuit if you do not understand how a vacuum tube works and what

the various voltages are for.

The depth of information on this forum from the experts all the way through to budding enthusiasts is astounding. I am very appreciative of the time and effort that goes into all the questions and responses. Learning so much. Thanks to all who take the time to contribute!

This stuff really sparks my interest though. Just getting back into HAM radio and was more attracted to these old hybrids vs the new stuff. I will go with the info you have given me and my limited test bench. When I fix this or if I get jammed up, I will email you directly. Thanks soooo much for the assistance. I will also post here on the group the final fix.

49293. TS-520 Transmitter Issues

RE: TS-520 S/N 510281

Hello. I have been watching and studying this group for several months and using it to do my troubleshooting. This group helped me get my TS-830 back online. But with my old TS-520, I think I am at an impasse for my level of experience. I have had this 520 for over 30 years and it has served me well. It just recently developed transmitter issues on 10M first and now on 15M as well. First, I was not getting the ALC movement on 10M with TUNE but it is now happening on 15M. I now need to have the Carrier control fully CW to Tune with ALC on all the bands. I swapped out the 12BY7 as well as the finals with with no change in behavior. I suspect the Band switch or Driver Coil board. The switch wafers look more robust than the later hybrids but the RF deck in general looks like a bear to remove and work on. Does 520's have wafer rivet problems like the others? I would like to nail this as best as I can before I take it apart. I don't want to shot gun anymore especially if the RF board is apart.

Mods:
Installed a Fox Tango CW Filter using the Channel Select control to switch in and out (I installed this many years ago while in high school).

I recently replaced the caps and resistors under the final tube sockets minus the parasitic-suppressors.

From K4EAA, I replaced the HV filter caps as well as the screen and driver filter caps. I have the final cage kit but have not performed it yet.

Any help would be appreciated.

Thank you.

Rich, AA6VX

Here are my vitals:

Output power:
80M 125w
40M 120w
20M 120w
15M 50w - No ALC in Tune

Topic: 49293 Message: 49294

Rich,

The first 3 things that jumps out at me are the 6146 "TX" cathode voltages, pin 1, the 6146 screen voltages, pin 3, and the 6146 HV.

First, you say the 6146 screen voltage is -108VDC in RX then dropping to -97VDC in TX. That tells me there is a "negative" DC voltage applied to the 6146 screens possibly caused by the SG switch set to the OFF position. No current will flow in the 6146 final tubes with a negative voltage applied to the 6146 screen (SG switch set to OFF) and this includes the absences of 60ma idling current in USB or LSB TX on any band.

Second, you say the 6146 cathode voltage, pin 1, is "0VDC". while a negative voltage applied to the 6146 screen will prevent current flow in the 6146 screen and plate circuit, it does NOT prevent grid current (ALC) from flowing when the grids of the 6146 are positive (caused by the positive half of the RF drive sine wave being positive).

Lastly, you say the 6146 HV is +960VDC in RX, dropping to +818VDC in TX. That's not possible with a negative voltage applied to the 6146 screens. A negative voltage applied to the 6146 screen will prevent any current to flow in the 6146 plate circuit therefore the 6146 plate HV in TX will be the same 6146 plate HV as in RX, no voltage drop will occur in the 6146 plate circuit, hence TX HV will be +960VDC not +818VDC.

I would check the SG switch to ensure it is in the ON position, check the 6146 screen voltage to ensure it is a "positive" voltage of approximately +255VDC, then check the 6146 plate voltage. Check to ensure the USB or LSB TX IP idling current is set for 60ma. If 60ma is showing on the meter (meter switch set to IP), in USB/LSB TX, then the 6146 cathode voltage will be approximately .3VDC or 300mv. If you have 60ma indicated on the IP meter but your DC volt meter indicates 0VDC on the 6146 socket, pin 1, then your DC volt meter is bad, probably out of calibration.

For curiosity, what's the voltage (VTVM, RF probe) on the RF board at TP-1? Ought to be about 2V, by the schematic.

Also measure run the TX level diagram voltages, band switch on 10M (set the VFO somewhere in the middle of the range), the RF drive levels at TIF, the TX Mixer output, 12BY7 plate output, and 6146 control grid input. Watch yourself getting these measurements, high voltage procedures, be careful not to eat some B+.

I forgot to include this.

Since there is a negative voltage applied to the 6146 screens, a current will not flow in the 6146 screens circuit. Therefore, with no current flowing in the 6146 screens there will be no voltage drop in the 6146 screens circuit, hence the negative voltage on the 6146 screens will be the same in TX as it is in RX.

Your RF drive levels at input of Q3 TX Mixer look good. Maybe a little strong at TP-2 but OK.

Your levels of RF drive at output of Q3 at MD are not good on the higher bands. That can be due to the TX Mosfet Mixer Drain and the 12BY7A Control Grid not seeing the Mixer tuned circuits being switched in by the bandswitch or high resistance in the path.

Your RF drive levels at DP (plate of the 12BY7A driver tube) are low with exception of 80 meters. You should easily see around 160v P-P on 20 meters. If 80 was as low as the others I would tell you to try another driver tube and to measure the Driver tube dc voltages with emphasis on the Screen Grid. Having normal RF drive levels on 80 would seem to rule out bad driver tube and off spec DC voltages at the tube socket. Of course if you have low RF drive at the control grid of the Driver tube and normal dc voltages then it stands to reason that you will have low RF output in the plate circuit.

With normal operating bias voltage on the control grids of the 6146 finals (around -55 to -60vdc) you wont see good ALC indication unless you have around 45 rms rf volts at Pin 5. At 39 rms rf volts or lower will have transmit output, but no ALC indication. A lot of people live with this on 10 meters and think it is normal and of course it is not. It is common but not normal.

One thing you can try on 15 or 10 meters is to adjust T1 on the RF board to see if you can get some more RF drive. This transformer is part of the TX BPF so make note if its position so you can reset it if adjusting it doesnt improve RF drive levels on the higher bands. Adjusting it often makes difference between no and some ALC indication on 10 meters.

Also, it is normal for RF drive to fall off starting on 10 meters with these 12BY7A tubes as they are running full tilt in Class A. At some point in life span will start to notice this. Are you certain that you have a good spare?

Not as common to have bad bandswitch contacts on the TS520 as the later rigs, but a good idea to clean all the contacts especially on the Mixer and Drive coil hanging boards. I do that with a artist brush wetted with De0xit.

To get past the obvious bits:

I. I use deOxit D5 and F5 for switches and potentiometers.

II. I use a small foam applicator or a small brush after spraying a minimal amount into a 'watch glass.' (A piece of lab-ware, you might remember them if you took more than one semester of chemistry.)

III. The chemical alone does a pretty fair job, if you apply it two or three times and 'exercise' the switch or the pot.

IV. Some sort of mechanical aid ought to be able to assist WITHOUT mucking up the contacts, which is MY most feared outcome of actually touching a band switch or similar. (I cleaned up a VTVM that a friend found in his tool shed, stored in there for over two decades, maybe more than three. A good cleaning, LOTS of corrosion and a 'stuck' ohms adjust pot worked free and cleaned thoroughly, and it is even almost dead-on CALIBRATED, all ranges and modes. I do LOVE these old boat-anchors.)

V, Has anyone tried one of these:

http://www.mcmelectronics.com/product/JONARD-OB-1-3-/22-1235

I'd be curious if they worked, or how well they worked anyway. If you know they're rubbish, please say so. If nobody has tried one, I'll be ordering a sample, and let you know how well it does once I get it.

I have used Diamond contact burnishing tools for years. I apply the Deoxit to it. Just dont want to use files, emory boards or any real abrasives. I havent used this particular one but it looks similar. My tool is the Jonard version that has replaceable diamond coated blades. If you go to Jonards website and seach under Pocket Burnishers you will see it and the replacement blades.

Amazon sells same version of this MCM one you are asking about but made by GC.

You will get lots of arguments about burnishing relay contacts. Some claim you cannot burnish relay contacts especially in low current applications as it removes the silver or gold flashed coating. I think it is ok if you use good diamond tool and dont go crazy. I have never experienced a problem with burnishing.

I dont burnish bandswitch contacts as hard to access with the tool and very easy to bend contact and loose the contact pressure and wipe.

Mike, Terry & Will,

Thanks. I'm grateful for your comprehensive responses. This is exactly what I was looking for. I need to digest them and plan out my next steps. Maybe also re-review Mikes videos and links on the tubes. I'll try and confirm some of the measurements with the Oscope as well so as to make sure we're not going up the wrong tree. BTW..The paragraph on the 6146 pin 5 control grid bias threshold for 10M really scratched an itch for me.

First off I apologize for providing some bad measurements see my later comments. I had some family distractions this morning during my voltage checks.

I have some new subtle developments. After cleaning the contacts, ALC on 15M Tune came alive, but only at ¼ scale. I was able to get 90 watts out on the Bird. Again, the Carrier control must be fully CW (always – I'm nearly resigned at this point to epoxy it there) and as I TUNE the DRIVE for peak ALC in SEND, the needle decays downward.

The rig is still dismal on 10M. For a short time, I got a perky 125W out on both 80M & 40M. But now 80M exhibits the ALC decay as well during TUNE/SEND with dull dips in Ip and <100 watts out. 40M still responds well with good ALC peaking and sharp Ip dips of the PLATE along with 125W out.

I had the SG switch ON for my measurements before. But now I inspected the SG switch and did not like the solder joints on it. I reworked it and checked it with an ohm meter for functionality. I re-measured the tube voltages making sure the SG switch was ON.

I checked to ensure the USB TX IP idling current was set for 60ma. (I had it at 55ma before but adjusted to 60ma now) Then I re-measured the 6146 cathode voltage pin 1 and it was indeed .33 VDC. I had recorded a zero reading before due to my sloppiness.

I checked the 6146 screen voltage with my Fluke DVM and it was a "positive" voltage of +251VDC on Receive and +234 on Transmit. My previous negative measurement was on my VTVM. I'm not sure what is going on there. Maybe I was being sloppy again or distracted. I'll have to check out the polarity on the VTVM.

I checked the 6146 plate voltage:
V1/V2 Plate:
R T
+912 vdc +856 vdc

I checked 6146 pin 5. I don't have a HV RF probe. So I used the DVM and Oscope.
-Fluke: R T
-93 vdc -58 vdc

-Oscope on AC during transmit: 0.350 Vp-p

BTW, I can see no cracked cores in any of the slugs on the coils hanging cards. I did an alignment on the coil boards several months ago per the manual. 10M Drive was the bad actor during that session, of course. It didn't matter where I moved the slug.

The only basis I have for the condition of my spare driver tubes (1 from RF Parts and 1 from K4EAA) is that they all work well in my TS-830S.

I used DeOxit with an artist brush on the band switch contacts. The visible contacts appear in good shape but the contacts between the wafer and the board are impossible to inspect.

Since I had some gross errors in my original recorded measurements, I'll hold off on adjusting RF bd T1 to see your guys' thoughts on this update first.However, I have marked its current clocking.

Thanks again for the help. After many months lurking on this group I'm honored to be at your tutelage.

Rich,

VTVMs have "Positive" and "Negative" DC voltage measurement switch settings. You need to verify you have the VTVM in the correct polarity setting when measuring DC voltages. What make and model of VTVM are you using?

I just acquired a VFO-820 for my companion TS-820 (digital display) transceiver. When I use rotate the frequency knob on the remote VFO, the digital frequency display on the TS-820 is not smooth; that is, it is "jittery".

A friend lent me his VFO-820 and it worked perfectly with my TS-820. I am wondering if my remote VFO could somehow use a "shot" of DeOxit inside of the VFO on a particular component inside of the VFO housing? Any ideas?

Thanking all that lend a tip, de KO8S, Karl

ALC decay sure sounds like typical 12BY7A emission issue. Your spare tube may not be any good?

You can also monitor SG voltage on the Driver tube and Finals to make sure it isnt falling off under key down?

Can also monitor RF drive level and see where it is falling off and then focus your dc measurements at that particular stage (TX Mixer , Driver tube, Finals etc).

Terry K9TW

From: Mike W5RKL
Topic: 49305 Message: 49307

Karl,

The "jittery" indication on the 820's digital display is caused by a dirty VFO variable capacitor "shaft to frame" contact point.

The 820's VFO, both external VFO and internal VFO, have a small side panel that is held to the VFO enclosure with 2 Phillips head screws. Loosen one screws then remove the other screw. This will allow you to rotate the small panel so you have access to the variable capacitor's pivot point.

The pivot point connection is a very thin piece of metal that is in the shape of a fork that slides between the capacitor's shaft and the capacitor's frame. This thin piece of metal is fixed/attached to the capacitor's frame on one end and slide between the capacitor's variable shaft and pivot point on the other end. As the capacitor shaft (VFO knob) is rotated, the shaft which has the variable plates attached, is connected to the frame through the thin piece of metal.

The connection point where the thin metal "rubs" against the shaft gets dirty causing intermittent connection between the variable shaft and variable plates and the frame causing intermittent VFO operation.

Perform the following cleaning process with power to the VFO removed by turning the 820 OFF and removing the cable from the rear of the VFO.

DO NOT slide a screw driver or other tool between the shaft and the thin metal piece as you can cause the thin metal piece to bend, or worse break, which can easily worsen the problem.

Read and adhere to the warnings and precautions printed on the DeoXit and Canned air cans BEFORE you use either one!!! Some DeoXit is not flammable but some it so pay attention to the warnings on the can!! It only takes a small spark to ignite flammable DeoXit.

Apply a small amount of DeOxit to the pivot point, just enough to do the job, then rotate the VFO knob throughout it's travel in both direction several times. Use generous amounts of canned air, available at Walmart in their TV/DVD/CD/Cell phone section, to remove any/all dirt/corrosion and cleaner residue. Reconnect the VFO cable and power up the 820 and test for proper VFO operation. If the display is still jittery in some places on the VFO dial, repeat the cleaning process.

Once the cleaning of the VFO has eliminated the jittery VFO, put the place the cover plate back on and install the screw and tighten both screws. Be careful, it's easy to strip the threads of those small screws!!

I bought a TS-520 at the Plano Ham Convention a while back and finally got a chance to setup my shack, antenna (shorty 40 OCFD), etc. I can adjust ALC on 40 and 20m but only have a single tiny spot where I can do so on 15m, nothing at all on 10m. If I swipe the DRIVE back and forth very fast on 15m is when I get an indication on the meter, if I go slow I don't see this. It's pretty difficult to find this spot :)

I have tested the driver and finals, all are good. I also sprayed all the contacts of the band switch with deoxit. It's also been suggested that I test R5 & R6 on the HV unit board, I haven't done so yet.

Since I'm just a tech, this is a bit of a problem if I want to talk (or ever resell the radio). I'm doing all of these steps into a dummy load.

Kevin-k5kdt,

Congrats on your purchase and getting your shack set up.

Since you did not state..I am guessing that you have "no/little alc in tune" on the higher bands? I doubt that R's 5 & 6 on the HV board are your problem. IF they were, you would probably see the "NO ALC IN TUNE" on all bands. More than likely you have a dying 12by7a driver tube. Testing the driver and or the finals in a tubes tester, will tell you if they are "gassy," have shorts, etc. It will NOT tell you that they will work in the actual RF environment. As many group members will attest: have a KNOWN good driver and KNOWN good finals in the shack.

When monitoring the drive level(ALC) during key down..does the drive(alc) slowly drop down?
If so...probably failing driver tube

While monitoring final plate current " Ip" during key down...does the Ip slowly drop down?
If so...probably weak/failing final amplifier tube(s)

Check your HV(high voltage) using the panel meter..it may not be exact but it will give you an idea.....usually.. any more than a 10-12% drop of voltage when key down usually indicates weak/failing HV capacitor(s)....NOT GOOD.

Karl:

NO NO NO!

DO NOT follow this hamfisted advice. Do exactly as Mike W5RKL has directed.

The rotor shaft wiper contact is formed and heat treated phosphor bronze and has the proper curvature and spring temper to apply the correct contact pressure (very lite pressure) on the rotor shaft machined face. Any attempt to bend it (besides how would you bend a curved contact that is in contact with a shoulder?) will very likely result in you losing the contact. Some people apply screwdrivers and wooden of plastic tools to press against the contact as they apply the deoxit so it will migrate better between the two faces. I do not recommend that as it is very easy to take the bow or curve out of this contact ruining it. About only way you could get more pressure would be to unsolder and remove the contact, heat it, bend it and re-install it.

The fact is these contacts do not lose their spring temper. They do lose contact pressure due to people sticking tools in and wrecking them.

Also you do not want any rf currrent flowing thru the bearing ball and race. That is the entire reason you have a rotor shaft wiper. RF current thru the bearings would be intermittent at best. They are not intended as a path of RF current. Only time you would need to lube them is if the factory grease has dried out and not common in the TS520. It is a very high quality mechanical construction.

Cardwell in the 30s started with braided pig tails soldered to the rotor shafts and frames and soon abandoned them due to the drag that they presented. They tried carbon brushes and abandoned them due to conductive dust and wear. Phosphor bronze was adopted and shaped and heated to provide the correct spring temper. Phosphor bronze is also sell lubricating. Today BE is used and nickel and silver plating is employed in high power tank capacitors.

About the only way you have lost the spring temper contact pressure is if a previous owner had done just as JD has suggested and attempted to bend the contact. Only other way is if the rotor shaft axial limit adjustment nut has backed off and the rotor has shifted. The nut is secured by white paint and I have never seen one back off. Have seen it on the Plate Load capacitor, but not on any VFOs.

So please disregard this very poor advice and do exactly as Mike has directed. He understands how these things work and how you can address the intermittent condition.

Kevin:

Reputable sources are discussed here often.

You can buy Driver tubes from Ken K4EAA and if not right he will replace at his cost. RF Parts is a good source of Finals and if not right they will also replace them at no cost. There are other reputable suppliers.

Can buy off Ebay, but it can be a crap shoot unless you have found a seller similar to the two sources above that has a good right of return policy. Part of the problem from Sellers perspective is they have no way to know if you operated them properly. If you dont have proper operating bias can easily go into thermal runaway and be instantly damaged. Not as easy to have catastrophic damage from excess off resonance key down time.

NOS may mean never installed or energized in a transmitter after factory final testing but no way to tell with 100% certainty. Even if truely NOS the tube has been sitting on the shelf off gassing for 35 years and may arc over when energized.

I DC hi-pot all my spare 6246 finals prior to installing them but few folks have that kind of test set. I also rotate my spares annually when I do my spring tune up (blow out the dust, visual inspection, lube the fan bushings etc). Does no good to reach for a spare when you need it only to find out it is not viable.

Some install them in a rig like a Heath DX-60 and run them for awhile prior to installing in their KW hybrid. Best emission tester in the world is running in your rig with RF excitation and full plate current. Still others believe in "cooking" them with just the filaments on and I wont get involved in the "gettering" discussion again.

I have had good luck buying 12BY7A tubes at hamfest and always bring several home with me from the tube sellers. Not so good with the 6146 tubes at hamfests.

So yes it is a bit of a catch 22.

Terry K9TW

Karl:

I agree we need to encourage contributions and enjoy debates based on sound fundamental technical knowledge and experience. Of course "believes, folklore, and tribal knowledge" will also be proffered and sometimes no amount of logic will dispel the voodoo. The challenge for every one (same as for any Google search results) is sorting out the best practice from the good enough to the just plain wrong ie the bum dope.

If you think it would be a good idea to try to "improve the tension" of your VFOs air variable capacitor rotor wiper contact as was presented then have a ball. It is your radio.

I will stand with my advice that it is not a good idea to attempt to improve the tension. I would like to see a You Tube video of how that could be accomplished working thru the access window. You will not be the first person to poke around on the wiper contact with a screwdriver.

Have fun
Terry K9TW

Kevin,

You are getting a lot of info in a short period of time that you may not fully understand. We are here to help, NOT confuse. We do not know your skill/knowledge level, the tools/equipment you have or, are available to you. If you want to continue to maintain these fine old rigs, you will need to obtain or have access to: a VTVM with an RF probe(many good older Heathkit ones ebay)..you can build your own RF probe--cheap) or any other decent/accurate meter that can measure AC/DC and RF voltage(with associated probe), the operators & service manual, correct sizes of "tuning wands" and further down the line an RF signal generator and o'scope.

But we're getting too far ahead. As stated: Ken Kemski (k4eaa.com) has driver tubes of quality.

Your problem may not be a bad driver...but maladjusted coils in the final amplifier string. Do you know the history of this rig?? The "Golden Screwdriver" may have been used..or other "modifications" done.

I don't want to sound harsh....but we can only assist you with what you observe and tell us...and accuracy helps. Terry-k9tw, Mike-w5rkl, and several others, are tops in helping diagnose and fix what is wrong...but even they can only go on what is told to them.

So PLEASE take no offense...we are here to help!

I have an inexpensive VOM and that is all. I have access to other equipment but it would be through my club.
I'm pretty good with electronics, I know how they work - I started college for EE but moved to software because I found it to be 'more fun' :)

I don't have any history at all, I'm searching my archives for the name of the guy I bought it from so I can ask him.

What's strange to me is that I can dip on 15M when I turn the radio on but after 10 minutes, no go. (And, to be clear, nothing happens on 10m).

Kevin,

I recommend you take voltage measurements before the problem occurs (when the radio is first powered up) and after the problem occurs (when you lose the IP current dip).

Before you perform any voltage checks of the final amplifier, check the cathode resistors to ensure they have not fallen out of tolerance. The ohm meter when connected between pin 1 and chassis opn the 6146 tube socket should show approximately 5 ohms. If the resistance is significantly higher such as 7 or 8 ohms then replace all of the cathode resistors. The TS-520 and TS-820 has two 10 ohm 1 watt cathode resistors while the TS-530 and TS-830 have four 20 ohm 1/2 watt cathode resistors. The 100 ohm 1/2 watt screen resistors typically do not need replacing but check them to be sure. Metal Film resistors are fine as replacements for the cathode resistors.

The 6146 cathode resistance, if significantly out of tolerance, will affect the "accuracy" of the IP meter indications so make sure they are good. I have a video on my website that discusses the 6146 cathode circuit resistance and how the IP meter display is affected if the cathode resistors are out of tolerance.

www.w5rkl.com

Ensure the bias setting is done correctly before you perform any voltage measurements. Follow what the operator's manual says. The bias pot setting that results in 60ma idling current flowing in the final tubes is the correct bias setting for proper Class AB1 linear amplifier operation.

Make sure the SG switch on the rear panel is set to the correct setting which is "ON". This switch should be checked after handling the radio, such as moving it from the operating desk to the bench and vice versa. Moving the radio quite often has cause the person's hand/finger(s) to accidentally move the switch to the OFF position so check it to be sure it's in the ON position. If you find a "negative" voltage on the final tube screens, pin 3, when measuring voltages on the 6146, then the SG switch is in the wrong position or there is a problem with the SG switch circuit.

I am cleaning the shack and ran across a TS-520 Service Manual and a DG5-Manual.
They are in good shape and complete. They are easily available as a download, but if they would help someone here I would be happy to mail one to you. I am down to an 830S and 530 so it is time they
went to someone who can use them. Doesn't seem right to put them on EBay if one of you can use them.
Best Regards,
Kevin

Thanks again Terry! These Kenwood Hybrids and it's accessories, are getting very old and precious, I will always use caution when I am using them! A couple of months ago, my friend gave me his Kenwood station; TS-820, MC-50 mic, speaker and 2-meter transverter that he hadn't used in 25 years or so. He bought all of this brand new when it first came out. The TS-820 was only opened up once when he bought it to add the CW filter and it has never been opened since! I would be rather reluctant to replace any of it's original components such as the HV caps, etc; but perhaps, I should consider doing so. The only thing that I have added to it, is a remote VFO-820 which looks mint, but requires the service procedure that you and Mike suggested in an earlier email. 73, de Karl, KO8S

49329. DC Hi-pot Testing 6146 Tubes

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-15 17:05:01 UTC
From: wagstw46@...
Topic: 49329 Message: 49329

Recently have had some off Reflector questions about Hi-pot testing that include the following:

1. 1. Do you have pictures of your Hi-pot? Yes- two pictures are posted on my website k9tw.com.

2. 2. Do you have a schematic of your Hi-pot? Yes-hand drawn not a nice Tiny Cad.

3. 3. Do you have a written test procedure for 6146 tubes? No- Have some good notes but need to draft the procedure I use and post on my website. Basically follow Eimac Bulletin #28 with modified voltage levels and leakage current acceptance criteria for the lower anode voltage swing of a 6146 (approx 1600 volts).

4. 4. If I send my newly purchased “NOS” 6146 tubes to you will you Hi-pot them and how much would you charge? Yes- I can and have done it and no charge. However, I don’t really want to offer it as a service due to shipping costs and risk of damage in transit. Also see #5 below.

5. 5. If I send them to you and you test and they pass what level of assurance do I have they won’t fail in service? I can’t provide you any assurance that they will not fail. However, if they can hold off 2.0kv to 2.5kv it is unlikely that they will arc over in service. If they arc over at 1000vdc to 1500vdc sometimes they can hold off around 2kv on the 2nd pass, but those tubes make me nervous.

6. 6. Will your Hi-pot tester damage my tubes? No- the Hi-pot is limited to 50ua current at 5kv with the test leads shorted. That level of current doesn’t produce any power (approx 250mw) that would exceed any of the tube elements dissipation ratings.

My design is essentially a copy of Richard Measures AG6K and Bill Jones K8CU designs. You can see their designs on their websites. You can also search under High Voltage Breakdown Testers.

In the 2nd picture you can see a 6146 breaking down at approx 2050vdc. I use a 1gig 1% meter scaling resistor that gives me a accurate 100X multiplier on a 10 meg voltmeter. In the picture you will see the voltmeter on the 30vdc range which is now 0 to 3000vdc range. What you cannot see is the ua leakage current meter needle spiking and dropping back. Of course cannot capture that action in a still photo.

I probably have close to $150 in my Hi-pot (a lot of it in the ¼” plexiglass enclosure). Cost depends on your junk box, hamfests finds, and ebay purchases. You can use oil ignition transformers, neon sign transformers, electric fence charger transformer, copy machine power supply, microwave oven transformers, and tube Plate transformers. I used a Stancor 2400vac Plate transformer and a voltage doubler. The caution here is that a Plate transformer is capable of delivering milliamperes of current and can kill you if the test set is not properly current limited. You have to decide what tubes you want to test and what anode swing they see in service to decide the output voltage level you need. For most common tubes a 15kv test set would be max you would need. For example if your linear is

running 4kv on the anodes than you will need at a minimum an 8kv test set so would probably build a 10kv set. Can be done with doublers and quadruplers.

For testing 6146 tubes you can make a very simple DC Hi-pot by using an Ozone generator transformer. A 3kv unit that has 12vdc input would be perfect for testing 6146 tubes (if you have a bench variac they also have 120vac units). You can see these ion generator transformers on Ebay for around $20.00 to $30.00. Could vary the 12vdc input with dc bench supply or use a series rheostat/pot. Much cheaper than a variac. If you don’t meter it and just use bench test equipment to measure the output voltage and leakage current you can greatly reduce the costs. A 50ua movement can be had on ebay for $20 and much cheaper at hamfests.

A 1 gigohm resistor (from an old TV 2nd anode high voltage probe) in series with your 10 meg DMM or VTVM plus lead will allow your meter to read 100X whatever dc range you use. I commonly use the 30vdc and 100vdc ranges, which allows me to read 3000vdc and 10,000vdc. Of course you could build the voltmeter into the test set and calibrate its meter face. I chose to just use the scaling resistor and bring the HV out to banana jacks and use good 10 meg input multimeter to monitor output voltage. You don’t need a zero center ua meter movement. This is just one that I had in junk box.

As soon as I get the 6146 test procedure finalized I will post it under How To or FAQ section on my website. I do some prep like wiping off the glass envelope and shield ring with alcohol wipes so wont track across the outside and testing the Hi-pot with open test leads to ensure no leakage current is registered. At higher voltages would place tube in a glass dish, but not necessary for a 6146 tube.

Remember a DC Hi-pot is also good for testing things other than vacuum tubes, transistors, and diodes. It works great to test air and vacuum variable capacitors. It is interesting to see where the KW hybrid plate loading capacitor arcs over at (it has what is referred to as broadcast band plate spacing).

If you have many more questions we can take it off the Reflector.

Terry K9TW

Terry,
What a coincidence about this subject. I'm getting ready to start building my own Hi-Pot tester. I just acquired the oil furnace ignition transformer on Ebay, and I need just a few of the HV resistors & some Plexiglas sheet.
Yes, Richard Measures AG6K and Bill Jones K8CU are good sources on these testers.

From: wagstw46@...
Topic: 49329 Message: 49331

Well for some reason I have had several off list emails in last couple of weeks about hi-pot testing and I just did 4 tubes for a real good guy who had some arc overs in his TS830 and two of the four were bad with one having a bolted fault from SG to Control grid. About worse thing you can have happen as it applies SG voltage back down the FG line to the -C supply and usually does a lot of damage to a KW hybrid. I have seen about 3 of these and not fun.

I used 12kv piv microwave oven diodes and .01uf 10kv wvdc caps in voltage doubler config and mounted them on glazed porcelain stand off insulators. I use 50meg series resistor to limit the current and old fashioned 100 watt lite bulb in primary of the transformer.

I had another 50ua meter movement that I measured the internal R and was going to use it with a 200meg series meter multiplier resistor to have a voltmeter on the front panel, but decided to just install some jacks and use a good bench test meter with 100X multiplier resistor to read the voltage. I wanted pretty accurate voltage measurement and I am not good and making nice new meter scales.

I always make sure the line cord is unplugged before I connect any DUT. I did not install a pilot lamp as didnt want a burned out indicator to lull me into a trap. Probable could have not used an On-Off switch as I say I always unplug it when making connections. Used some good quality flexible Belden HV test prod wire for test leads.

Just be careful.

Terry K9TW

I'm in the lucky position of having a 530S, 530SP, and 830S Gold Label. As such, I'm selling my TS-530SP.

Its on ebay, currently in auction, but with a buy-it-now price of 275ukp, plus postage. Already offering to pay insurance for UK delivery on buy-it-now, but if a group member buys, I'll try to work out a better deal too. The description also includes a video to it working (RX and TX), and an edit links to a video showing it does DLP tune on the lower bands - which I didn't test before as I don't have an antenna.

Apologies if ebay linking breaks rules (had a quick gander and couldn't owt specifically forbidding it)

Troubleshooting Continued
TS-520 S/N 510281

I have four spare 12BY7's, plus the one in the 520 and the one in the 830S for a total of 6. I tuned up the 520 with 5 of my driver tubes. They all provided very slight different drive levels on the lower bands and were able to provide ALC readings with my Carrier control full CW except for 10M where I still get nil. 80M-20M I can get roughly ¼ scale ALC reading with the Carrier control down to 1 o'clock. I adjusted T1 for peak ALC which helped a little on 15M but no change on 10M. I probably should run all the tubes in the 830 again just to give me more assurance of the RF capability of all my spare driver tubes.

I saw some erratic ALC needle movement for a time that correlated with erratic DP/DRV DC voltage on my VTVM. This may be the ALC decay-like behavior I saw before but it seems to have gone away for the moment so I have an intermittent problem there. I did not see any erratic DC voltage behavior on pin 5 of the 6146. Could C3 be going bad? However, I'm still dealing with a sustained reduction in drive/power regardless of the intermittent.

My VTVM is a Heathkit V-7A restored, upgraded and calibrated by Gary Clarke on eBay. As a side, I made an N5ESE single diode RF Probe I use with the VTVM. I also have a Fluke 85 RF probe to go with my Fluke 87III DVM. The readings are not always consistent between the two RF probes but I guess they're "ball park".

I plan to make some 10M only TX diagram measurements when I get a chance. I updated my vitals alittle below.

Thanks
Rich, AA6VX

--
Corrected and Updated Results

Output power (Carrier fully CW):
80M 125w…sometimes 90W

At DP you are measuring the Plate voltage of the Driver Tube if you are using a VTVM on the DC ranges.

If you are seeing erratic Plate voltage regardless of the installed driver tube you might want to look at the tube socket solder connections on the RF board. You can view them by looking thru the hanging boards and pressing and pulling on the Driver tube to see if any of them are cracked. You can see them between the last metal shield and the Drive coil board. Pretty common problem as the board is flexed with install and remove of the 1`2BY7A tubes.

If solder connections are good and Plate voltage is varying I would look at SG voltage and Bias voltage on control grid to see if either of them are varying. Also Cathode voltage should be varying along with the Plate voltage as plate current will be varying and the IR drop across the three cathode resistors will vary .

Also I hope you know you cant use either of your RF probes at DP or DRV as the RF voltage will exceed the PIV of the single germanium signal diode in the probes. Need a three diode probe or use your O-scope. It appears you are using your O-scope to look at RF drive at DP/DRV.

49338. Using a TS 520 off a fully charged battery

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-16 16:25:30 UTC

Topic: 49338 Message: 49338

I am planning my first mini field day on a mountain close to Las Vegas. As a HOA home owner this is a chance to try new antennas. My question to the group is what is the voltage range to safely operate the 520? I have a brand new SLA 35 AH battery that I charged last night. The readings with the charger removed is 13.76 VDC.
At what voltage should I stop using the 520?

Gary

I assume, Gary, that your 520 is equipped with the DC to DC converter (X46-1000-00), mounted and connected to the 520 on the rear panel.

I personally would not attempt to operate the TS-520 on DC power if the battery voltage drops below +12.0VDC. You should know the TS-520's DC power requirements which are listed in the TS-520's operator's manual. This should be the first thing you do. The current demand based on the following will give you some idea what limitations you will be up against.

1. Heaters OFF, receive ONLY, 600ma
2. Heaters ON, receive but ready to transmit, 5 amps
3. Heaters ON, full xmit power, 15 amps

Note:
RCA and other tube manufactures specify a minimum of 60 second warm up period for the 6146B. Therefore, flipping the HEATER switch ON will require you to wait at least 60 seconds before you should attempt to transmit in any mode. TUNE up which will require longer transmit periods will also affect the life of the battery.

If you operate low power then the current demand placed on the battery will be less than if you operate full power. Naturally, to operate low power on SSB, you will have to build a simple variable DC "negative" source to control power output in SSB mode. This simply circuit is connected to the "External ALC" connection on the pin 6 of the rear panel 8 pin REMOTE socket. You can find this circuit on the Yahoo Kenwood Group homepage in the "Files" section. Simply turning the MIC gain down will not accomplish QRP operation in SSB mode. The CAR control will reduce power in CW mode so an external ALC negative voltage circuit will not be required since ALC is not used in CW mode.

Therefore, I'm not sure how long you will be able to operate the TS-520 using a 13.67VDC 35 AH battery.

If it is not equipped with the DC to DC converter, the 520 will not like an inverter that is not
sine wave, or at least a UPS (Uninterrupted Power Supply) used for computers retrofitted to
use a larger capacity battery.
Either way, unless you're using a solar panel to keep the battery going, I don't think the 35amp/hr battery will last very long, especially if you have to use an inverter which robs
efficiency.
I ran a solar powered voice station on Field Day from start to finish using a TS-2000 at
100 watts, a 105 amp/hr glass mat deep cycle battery and a 50 watt solar panel without
a problem. I run my shack on solar; two 100 watt panels, four 115amp/hr deep cycle batteries but I do not run the TS-830S on solar/batt power.
Do run wifi, router, phone, a couple of led lights and a laptop here and there as well as a
Yaesu 897D and a 65w 2m radio that I rarely use on solar/batt power.

11.6V (UNLOADED)

is the absolute lowest you should go with an SLA battery without risking damage to the cell connections, the plates, or the gelled acid compound itself (crystallization and drying out). If you keep it at or above 11.9V (UNLOADED) you will maximize the life and number of charge cycles the battery will take over its life.

If you go on and take that last 0.3V of use many times, well, you won't -harm- the battery, but you will lower the number of charge cycles it will take over its total (shortened) life span.

If you go on and keep using the battery, and get the battery down to

10.5V (UNLOADED)

even ONCE, what you now have is a dead, unusable, unchargeable, useless, used-to-be-a battery. After you dump it to or below 10.5V, and then recharge it, the battery will appear to take a charge, but when you put a load on, it will drop almost instantly back down to 10.5 or lower. ("Almost instantly" means in less than five percent of the usual, undamaged discharge time. Can be as little as one percent.)

You've already got the sealed lead-acid (gel cell, undoubtedly). Next time you go for another battery, look around for "absorbed glass matt" (AGM) batteries instead.

Gel cells just flat don't cut it for a lot of applications, and the crystallized gel and sulfation problems have given me more grief over the years, everything from alarm panels to industrial process sensor and control backups, to radio applications. The AGM batteries do all the good stuff that gel cells do but are a lot more robust, harder to damage, and resistant to abuse.

Terry,

Yes. Thank you. I do put the RF probes away when I'm on the right end of the TX diagram. I made my official measurements on the scope but was using the VTVM regular leads straight onto DP when looking for the decay/intermittent.

I've looked at the socket solder joints a few times but not while flexing the board from the tube side. I will try that.

What is your thoughts on those wire wrap terminals? I tried to add solder to them using a little flux but they had a hard time accepting the solder. Is it common for those to grow in resistance?

Rich AA6VX

Rich:

No wire wrap makes a very good electrical connection assuming they have not been tampered with and are the original factory wraps. They are low contact resistance and last indefinitely. The wrapped contact area is essentially gas impermeable due to the very high contact pressure so they dont oxidize.

Only bad ones I have ever seen are the cobbled up attempt of re-wrapping and soldering. Almost all are cold solder joints. See that a lot if a "hanging board" has been replaced.

No you cannot solder to them very well due to external oxidation over the years. When I have to unwrap one I cut back all of the original conductor as it gets work hardened during the wrapping process and cant be re-wrapped. There is usually not enough slack to expose new conductor and re-wrap and you must use proper hand wrapping tool. I have one but never use it. Absent ability to re-wrap properly I lightly file the post to get to clean metal and make one or two wraps at the top with the new lead wire and then solder it.

Topic: 66 Message: 49345

First, you need to sign your messages with your name and call sign at the end of the message.

Second, do you have the TS-820 operator's manual with the schematic? There is a TS-820S high resolution schematic and the operator's manual you can download from my website, use the links below:

http://w5rkl.com/wp-content/uploads/2014/04/TS-820-hi-res-schematic.pdf

http://w5rkl.com/wp-content/uploads/2014/04/TS-820S-Operators-Manual.pdf

The remote VFO-520 and VFO-820 operator manuals can be downloaded at the following links

http://w5rkl.com/wp-content/uploads/2014/04/VFO-520-operator-manual.pdf

http://w5rkl.com/wp-content/uploads/2014/04/VFO-820-operating_manual.pdf

I have no idea what the "pig tail" is, you will have to trace the pig tail wiring to it's destination. That's obviously a previous owner mod/addition. Its a shame but most changes made by previous owners are not documented, leaving any new owners out in the dark as to what the changes are for.

You need to check the wiring at the wiring side of the 820's Remote VFO socket. The factory wiring for the Remote VFO is as follows.

Pin 1 is the VFO signal coax center conductor (connects to the internal VFO through an RCA plug)

Pin 2 is is the VFO signal coax shield (part of the connection in Pin 1 to the internal VFO)

Pin 3 is ground

Pin 4 is 12VDC for the VFO lamps

Pin 5 is the VFO's relay (used for split operation, see the operator's manual details for VFO, VFO R, FIX R and FIX operation)

Pin 6 is the Function switch CAL RMT setting allowing the remote VFO to zero beat with the 820's calibrator at every 25Khz intervals except the remote VFO is used instead of the 820's internal VFO (see the manual for futher details)

Pin 7 is not use

Pin 8 is connected to the internal VFO's B+ terminal (a jumper between this pin and pin 9 provides B+ for the internal VFO)

Pin 9 is 9VDC (provide 9VDC power for the internal VFO, see pin 8 above. This also provide B+ for the Remote VFO when the remote VFO's Function switch is set to a position other than OFF)

The VFO-520 and VFO-820 are the same VFO. The wiring and cable are the same. This means you can plug a VFO-520 into the TS-820's remote VFO socket and vice verse, a VFO-820 can be plugged into a TS-520's remote VFO socket without any wiring changes.

Since the Remote VFO is working with your other 520/820 radios then it stands to reason the remote VFO and cable are not the source of your problem. More than likely a previous owner has made some undocumented changes to the 820's remote VFO socket.

I've got the 60ma set correctly. I was receiving some information about potentially having a failed / maladjusted oscillator on 10mtr but I screwed up one of the tests and so the other party left the conversation.

I am going to see if I can adjust the 10mtr oscillator - to get it oscillating again; off to Frys to get some adjustment tools for the slugs.

Note that I've check and my crystals have not been modified - at least I can attest that 2 of the 3 for 10mtr are ok, the 3rd is not viewable because of orientation.

Kevin K5KDT

One other item that I noted to the other party, I do get receive on 10mtr.

49348. Alignment question 830s

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-17 15:13:00 UTC
From: n612dw@...
Topic: 49348 Message: 49348

Hi gang,

reading the service manual and trying the alignment procedure - reading from the "Adjustments" table steps 3-6 to verify/set the carrier points and IF Shift. I just installed the 500 hz CW filters after finding them online and want to make sure its setup correctly so that the VBT and such works as expected. The radio is working fine so far otherwise.

I seem to get quite a bit of attenuation on the narrow filters with the jumper set to the CW4 settings (recommended when both filters are inserted). I expect some additional attenuation, but it seems excessive (like nearly 3 S-units on the gauge). How much is expected? from what I read, I should only have at most an "S" unit or ~6db difference in loss between narrow and wide.

I realize the S-Meter may not be too accurate and I can get a very accurate measurement of the loss when i put my HP signal generator on it later when I drag it out. But offhand it does seem excessive, which is why I wanted to check/set the carrier /IF shift point adjustments.

Question-
Item #3/4 Carrier Adjustment - table suggests that with the counter attached to TP3, you use TC2 to adjust the LSB frequency of 8828.50 kHz and TC3 for USB of 8831.5 kHz adjustment on the IF board to . However, I do NOT get any change when moving TC2 OR TC3.

Oddly, I CAN readily adjust the 8375 frequency when attached to TP1 (although the freq counter 1meg input seems to suck out the signal a bit at this point) with TC2. But adjusting TC3 just doesnt seem to move the frequency at TP3 of 8831.50 in USB.

How can this be so? I feel stupid/silly here. What the heck an I missing? I also must be blind, as I cant find TC3 on the schematic. Are there any misprints in the doc?

once I fiddle with this a bit and comfortable with the adjustments, I'll likely sweep it with the generator to align it like the "Survival-Guide" suggests to that it matches the filters I have exactly.

Joe,

The "original equipment" 9 pin plug is VERY hard to find...as you have found out..and IF you find one...a premium price is wanted. Numerous folks have just used the "9 pin socket saver" type of plug...or others have used a non-functional 9 pin based vacuum tube...and broke the tube open and used the 9 pin base..others... at times(me included) have just used a good piece of stiff wire between pins 8 & 9.

Bob:

It sounds to me like you are adjusting TC-2 and TC-3 on the IF board? If so, please move to the PLL board.

TC-2 and TC-3 Carrier Osc trimmer caps are readily available thru holes provided in the bottom cover. See Pg 43 of the 3rd edition of the service manual. The frequencies noted in Step 3 are just starting points. Step 30 is where you will do the real alignment for proper SSB frequency response.

Now that you have messed with the VBT oscillator trimmer TC-2 I would set it back to 8375.00 as a starting point. I would get on TP-1 using an O-scope 10:1 probe to input to the frequency counter.

Lacking test gear to perform Step 23 you can use the S-meter zero beat method that Richard Measures describes in the Survival Guide Maintenance Sect to align the VBT oscillator later. The acceptance criteria waveform depicted in Step 23 prime is wrong. It should be same as shown in 23. You want to see a nice AM or DSB signal with good crisp zero crossing.

Hi Joe and Neil,
Thanks for taking the time to answer my questions. Yes, I did watch the video and come to realize that instructions in the video are more or less the same as the instructions I listed down which came with my radio.

I wanted to know what the bias and RF volts adjustment did and I guess you answered that Joe. And yes, I realize now, after using the radio for awhile, that the Bias doesn't need to be readjusted as it remains at the 60 mA reading once set.

I'll have a look at the home page and try to read up more about the other functions.

Cheers
Mark

egads...

this is what i meant by stupid... duh !

i dont think things are messed up badly as i just barely made an adjustment to observe, and moved it where i thought it was prior, an stopped since something wasn't right.

i have a pretty good set of test equipment at my disposal so that's not really a problem, all except for a good RF Spectrum Analyzer (too much buckage for my little usage).

tnx terry, i missed it because i was looking at the "unit" column of the measurement, NOT the "unit" column for the adjustment. Limitations of the screen size when looking at a PDF file got me.

now its obvious... all i can do is chuckle at myself at this point ! :-)

tnx agn

49354. Drifting

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-18 05:26:15 UTC
From: k0spn.ae@...
Topic: 49354 Message: 49354

Minor problem with my 530 and I'm thinking it's an easy fix, but need some suggestions.

First, drifting may not be the right term, but every five or so times I fire up the 530, I can watch the display (and hear) the radio drift up and down 400-800Hz over periods of 15-30 seconds. Even after warming up for several minutes it still does this, but if I switch it off for 10 seconds and then back on it's back to a small amount of drift for a short bit, then it's pretty solid.

I know that it's going to shift a bit as it warms up but the huge swings are the problem is, so I suspect that an electrolytic or two are weak and rather than wholesale replace the lot, I'd rather just fix what's ailing.
I did replace the power supply and HV caps about a year ago so I don't think that is the issue.

Sadly, I don't have the time to spend lately to troubleshoot everything, and it isn't my best area to begin with, coupled with other projects I'm working on, and I'd like for you knowledgeable souls to point me at some likely culprits to check to remedy this situation.

Cheers.

Brent,

You need to add a signature at the end of your messages. All members who post messages or respond to questions on this group must add a signature to the end of their messages. When your application for membership was approved the group server sent you a couple of messages you should have read. These message contain the group rules, policies, and stated what an acceptable signature is.

I recommend you review those messages again and add signatures to every message you post on the group.

Not stupid just need to get more familiar with the service manual format and the radio physical layout and test point locations.

About 90% of time if you dont get the expected results when adjusting a trim pot, slug tuned coil, or trim capacitor you are on the wrong test point or adjusting the wrong device. Sometimes can be a problem with the test gear and associated test cables, but more commonly wrong test point or wrong adjustment is being used.

Adjusting Carrier Oscillators isnt going to affect your frequency response of your new 500hz filter, but should do it to ensure you have proper SSB frequency response. In addition to doing the audio injection wattmeter method you can use audio spectrum analyzer software like Spectrogram which does a great job and certainly a few bucks cheaper than a Spectrum Analyzer. I give all my customers a copy of Spectrogram as left response curves. Of course has element of personal preference to it and free to set to more bass or more treble presence. That is why KW gives easy access thru bottom cover holes. Even moving and banging the rig around can move the trimmer cap positions.

It doesnt take much movement of TC-3 on IF board to produce carrier on your SSB output signal. I usually exercise these trimmers multiple times lock to lock before adjusting as they can sit in one spot for a very long time and get very touchy when you try to adjust. Ok to use a little Deoxit as well.

Simple check is to do a single tone test. You inject 1khz audio into the mic line and use an O-scope with an inline RF sample device (a dummy load with a capacitive sniffer, a coax tee with resistive or capacitive divider, wrap a coil around the coax jumper, or use a 40dB attenuator tap).

Connect rig to dummy load with external wattmeter in line and the RF tap.

Use approx 7mv of audio. Adjust the mic gain for approx half power (no more than 50 watts as you will be running key down longer than normal). If Carrier suppression is not adjusted properly you will see the 1khz ripple on the envelope.

If you search on this subject can see various test set ups including pictures of the O-scope waveform. Can also see unwanted or opposite sideband suppression. Subject for another day.

Brent:

Not being critical but why does a bad electrolytic come to mind? I see this a lot for various operating issues and dont understand it.

If it quits drifting up and down with time and cycling power on and off how does the bad electrolytic get better?

I would do simple thing first and that would be to clean the VFO air variable capacitor rotor shaft wiper contact.

How to do this has been covered numerous times. Most recently by Mike W5RKL. Search on message 49307.

Have to pull the VFO to do this. Observe caution when re-installing so you dont pinch the VFO pilot lamp power leads.

If this doesnt help come back.

Greetings Group!

  Over the past month or so, this group has seen a surge in membership. What saddens me the mostis that "newly added members" fail to read the "WELCOME MSG" that is auto-sent to them upon granting of membership.

So you don't have to waste your time looking for it, I'll give you the short version: ALL POSTS/MSGS WILL HAVE AN ATTACHED NAME(Christian/first name) AND CALL SIGN(if any).

Mike-w5rkl(group moderator) and myself, Joe-wb7uqu(group co-owner) have spent too much time "reminding" members to properly sign their posts as required by group policy.

SO, let it be known that: For "moderated members," offending party/parties will be warned ONCE, and after that...any further post/msg will be rejectedunless properly signed. For "un-moderated" members, you get that same warning...then if there is non-compliance...you will be put on "moderate."

You can set up your "Yahoo email" account to automatically add your required information:

   Look in the upper RIGHT HAND CORNER of your "yahoo mail page." Look for the "cog wheel" symbol, put cursor over it, a drop down box will open, click on "settings," click on "writing email" enter required information in the rectangular box...you can even select font type and size and save.

Thanks for your attention to this matter.....

49364. DC Hi-pot Testing of 6146 Final Tubes

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-20 02:15:35 UTC
From: wagstw46@...
Topic: 49364 Message: 49364

I added a write up about DC Hi-pot testing of 6146 final tubes under the How To section on my website k9tw.com. If you have questions please email me off the Reflector.

I had several questions from people who viewed the pictures of the test set worth sharing.

1. YES- the tester has a cover. It is a simple double U box construction. I had the top U cover off as I had just changed out the .01uf 4000wvdc filter caps for a pair of .015uf 10,000wvdc caps which gave me more head room. I normally do not have the cover off. I should have put the cover back on before taking the pictures. NO- it is not unsafe to run with the cover off. It is no more unsafe than with the PA cage cover off of your KW hybrid in order to observe source of arcing or to measure anode voltage. No more unsafe than defeating the lid interlock on your high power linear amplifier. You must be aware that you are within reaching and falling distance of high voltage and must utilize proper safe work practices when any cover is removed for access to high voltage circuits. It is a part of our hobby and part of being a technical and thinking person.

2. NO- I am not concerned about tracking or leakage across the base board. It is a piece of aspen that I had and I applied three coats of clear polyurethane varnish to it and the high voltage components are all mounted on 1 inch glazed porcelain standoff insulators. The low voltage components are all terminated on barrier terminal strips. There is no leakage or tracking across this board.

3. NO- I do not want a pilot lamp to tell me if the unit is powered on. I have room for one below the On-Off switch and I decided not to install it as I do not want a burned out lamp to fool me in to thinking the power is off. I always unplug the line cord from the 120vac when connecting or disconnecting any DUT (device under test) to the test set. It does not take long for the filter caps to bleed off after unit is de-energized.

I am pleased that several people had questions about safety.

49365. No ALC Indication and only 3W output

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-19 21:54:08 UTC
From: peterlake2003@...
Topic: 49365 Message: 49365

Hi
Had a fault with this TS520s that damaged the FET shown as Q3 on the schematic of the RF Board, the FET fitted was a 3SK40, I was not able to get this but replaced it with a 3N212, this then brought the TIF signal through this stage.
The symptoms I have now are:-
Normal Bias Levels of 60mA on SSB no signal
60mA at tune Switch to CW this increases to 100mA
Into a dummy load on 14MHz I can see at tune a power level of 1W
when in tune and 3W in CW.
All of the voltages seem to be present and correct.
Reading else where I see that the ALC indication is a direct indicator of the performance of the driver so my question is Should I suspect the driver?
and is there any test I can do to prove this is the fault?
Any help would be appreciated.
Thanks
Peter

49366. TS-820S Mic/ALC Question

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-19 23:25:31 UTC
From: WQ8Q
Topic: 49366 Message: 49366

I have a recently acquired TS820S to go along with my TS-520.
I use a Kenwood MC-60A Mic for either of them, set at 50K impedance.
With the TS-520, I can easily accomplish maximum allowable ALC with the Mic control on about 2.5 and if I increase the Mic control, I can easily pin the ALC meter to the opposite side.
However, on the TS-820S I can just barely make max ALC and that's with strong voice peaks or whistle into the mic.
Normal speech just won't do it. And that is with the Mic control set on 2.5 - 3.
Increasing the Mic control to max does nothing to increase the ALC.
This is the same with or without the Processor on.

I was hoping to ask this question on the Saturday Kenwood Hybrid Net, but that hasn't been on for several weeks.

Any suggestions?

Peter

Q1 TX Mixer very seldom fails in service. Low RF drive at output of Q1 is more commonly due to low TIF input from the IF board or low or missing Het Osc input (local oscillator level needs to be approx 1.0vdc rms rf on all bands)

You say all voltages are OK. Do you mean RF signal voltages and DSGG DC voltages are OK? I suspect you mean DC voltages?

Usually when troubleshooting low RF drive you would take RF signal voltages first and where you find them not to spec then take DC voltages at the pins of the active device involved.

Pretty easy to measure RF drive levels if you have RF probe and VTVM or an O-scope. Look at TX Level Diagram in service manual for the levels you should see. At TP-2 (at Q1 TX Mixer) you should see approx 200mv and at MD you should see approx 2.0 rf volts. Take these with the SG switch off. Dont get on the Driver plate circuit with single diode RF probe.

If you have no way to measure the "goes ins " and "goes outs" at the TX Mixer then can do a simple Driver Stage test as follows (posted here many times).

1. Screen grid switch off
2. Heaters on
3 CW mode
4. CAR Level at 1200
5. Panel meter at ALC
6. VFO at approx 200
7. Drive Control at 1200

Flip to Send and peak the Drive control for full scale ALC indication. May need to increase the CAR level pot to get FSD indication. Leave rig keyed a few seconds to see if the ALC indication starts to slowly fall off FSD. First place to see this is usually on 10 meters and it is telling you that emission is down on the 12BY7A tube.

Repeat on all bands and let the Driver tube rest a few seconds between bands as it is running Class A with about 27ma Ip and runs pretty hot. If you can run this test it tells you that the Driver Stage is fine and that means all components (interstage coupling caps, parallel resonant tuned circuits in grid/plate circuit, bandswitch contacts, active devices, RF signal levels, operating bias voltages etc)

With exception of 10 meters you should be able to get FSD ALC indication with the CAR pot advanced no more than #3 to #4 position.

Topic: 49370 Message: 49370

Hello all,
I've been looking all over for some basic information on my TS-520 and have no luck at all. This is concerning the CW mode and the phone jack. The manual states that you need a 1/4" phone jack, but says nothing about whether it is just mono or stereo. Nothing is mentioned in this group either. Looks like everyone is either using a straight key or an electronic keyer.
I recently acquired a 1966 Vibroplex standard bug with 3 posts and this would use a stereo jack but I cannot tell if this would work properly on the 520. I'll have to make may own cable and I'd like to get it right the first time. Does the 520 even support this kind of key?
Thank you in advance for your help.

Hi Larry,

You can use either a MONO or STEREO 1/4" plug.

The only connections used on either a 1/4" MONO or STEREO plug are the
"TIP" and "SLEEVE".

The "TIP" is the keying voltage which is negative, approximately -65VDC.
The "SLEEVE" is the "GROUND".
The STEREO plug's "RING" connection is not used nor is it connected to
any key/bug/keyer output.

Most all electronic keyers will work and key the 520 transceivers
without any problem. However, make sure any keyer you use will key at
least -100VDC which most electronic keyers will do.

The 1/4" MONO plug does NOT have a "RING" connection, only a TIP and
SLEEVE. I should have included that in my response.

Larry,

Are you sure it is a "bug", a key with a long center spring-mounted arm with a weight at the end? My Original Standard bug has only 2 terminals and also has the two wire "wedge" plug and cord. I replaced the wedge cable with one wired with a TS (Tip, Sleeve) mono plug. Some newer rigs require that a straight key (or bug) be wired with a TRS plug but use only 2 of the 3 connections. The TS-520 uses a 1/4" mono, or TS plug

The VibroKeyer I have does have 3 terminals and needs a TRS (Tip, Ring, Sleeve) "stereo" plug. It is intended to be used with an electronic keyer, either internal to the rig or an external unit.

Peter

I forgot to mention that if you have no ALC indication on any band then the Driver stage test procedure I provided you will not work.

If this is the case then best way to troubleshoot is to run the TX Level Diagram to see where you are losing the RF drive voltage at. You will need more than 39rf volts at the control grids of the finals for any ALC indication.

Also, you can measure the operating bias at the 6146 final tubes and make sure it is switching from approx -100vdc cut-off bias in Rx mode to approx -55vdc operating bias in TX mode. If it is not, then no amount of normal RF voltage swing at the control grids will result in ALC indication as wont be able to make the control grid positive with respect to the cathode and no grid current can flow.

If operating bias voltage is normal and you have less than 39rf rms rf volts at control grids need to work your way back thru the Driver stage to see where you are losing it at.

Again I would start at TP-2 and measure TIF input to the new TX Mixer mosfet that you just put in (perhaps you have a bad 3N212?) and measure output at Drain of the new mixer at MD. I would also be 100% certain you didnt swap leads on the 3N212.

Larry, you must have a Vibroplex Iambic Paddle, as the semi-automatic bug uses only two terminals. The 520 only takes a 2 conductor plug . . . so for the paddles you would need an electronic keyer, and one which will key negative voltages (I think -65v on the 520)

A semi automatic bug plugs right into the hybrid line just like a straight key would.
You could use your paddles as a cootie key, but that's a whole 'nother ball game.

73 de Rick, WQ8Q (user of Vibroplex Bug AND GHD & TWanger cootie keys)

I didnt see any response relative to cleaning the VFO air variable rotor shaft wiper contact?

If that does not resolve your problem then next step would be to look at the regulated 9vdc to the VFO.

Absent a DMM or O-scope to monitor it you can try cleaning the voltage adjust trimmer pot VR-2 on the AF board.

Can also carefully remove clean and reseat Molex Conn 10 on the AF board, and lastly could exercise and clean the Mini-din switch inside the Ext VFO jack on rear panel. Usually if the mini-din or molex connector is bad the VFO will be intermittent or non-operational. A dirty VR-2 might act better after it gets some current thru it during the warm up phase?

After exercising and cleaning VR-2 you will need to set it so you have 9vdc at TP-6.

My 2 cent on drifting.
The boat anchors like my TS-820 are 30+ years old and so are all boards for the series.
Don't expect any board to be better or worse than the original one in the receiver.

When I got the TS-820 6 months ago I gave it an overhaul.
First I downloaded the service manual, and all additional info on faults and mods.
Checked all resistors in final and drive.(had to swap 4-6)
Then followed all adjustments according to TS-820 alignment manual.
Got 2 set new final and driver tubes (one for spare)
After figuring out drift were related to 9V rail I removed all bits in the regulator and installed a LM317 regulator, caps and resistors to get 9.00V
Removed the Zener and resistor for the 14V rail and installed a LM317 + additional bits to get 13.95V

I think most boat anchors owners believe every bit have to be the same as when the rig left the conveyor belt at the factory. I have to agree, but there is no excuse to drift or jump around the band. Some components and parts have to be sacrificed for new components to meet today's standard as far as possible. New voltage regulators are inexpensive and easy to install.
After 2 months I realized I still had problems. It was not represented when I had RIT pressed.
Traced it to the VR2 on the AF Board. It was removed and installed a fixed 4.3K resistor.
It was spot on (at least as close to to be 99% in middle of the RIT adjustment compared to when RIT is disengaged.
Looks like my 820 is working fine ATM.

Anfinn:

It has been suggested here several times over last couple of years to mod the radios with modern 3 terminal regulators.

Of course anyone is free to do so and modifying radios is the essence of the hobby for some folks.

The other option is to install "huff and puff" circuits and that has been addressed here as well. Again that is owners prerogative if they want to do that. There are at least two designs that work well.

However, there is no reason why a linear series pass regulator cannot be made to function to meet the original warm up and long term drift specs for any of the KW hybrids. Have to remember these radios were intended primarily for CW and SSB modes and not the so called modern digital modes some run today which require tighter specs. I am not familiar with running these modes with KW hybrids so dont know if need to mod the rig low voltage regulated supplies or not.

I troubleshoot and repair radios for KW hybrid owners and I try to return them back to factory Rx and Tx performance utilizing the as built design configurations. About only "mods" I do is to install substitute active devices when the originals can no longer be purchased. So my suggestions to all owners who come here for help will focus on how to fix the radio and not how to mod the radio.

Of course you and others are free to suggest modifications and some folks may appreciate and take your counsel.

As far as old design the 820PLL certainly falls into that category. You might want to look into replacing the Het Osc crystals for starters. Also, the digital display is constant source of problems and new technology has answers for that as well.

49379. Hybrid Legacy Net Update (July 20, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-21 00:33:09 UTC
From: Mark Gilger
Topic: 49379 Message: 49379

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday net was run by me, Stu, K4BOV. There were 15 stations checking in under good band conditions. We had the following number of radios checking in.

The Sunday net was run by me, WB0IQK. There were 12 stations checking in under good band conditions. We had the following number of radios checking in.

6 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
0 running TS-830S
0 running TS-511
0 running 599 twins

The reset were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 80, Sunday☐s total = 85
March 2014, Saturday☐s net total = 82, Sunday☐s total = 73
April 2014, Saturday☐s net total = 64, Sunday☐s total =43
May 2014, Saturday☐s net total = 66, Sunday☐s total = 35
June 2014, Saturday☐s net total = 43, Sunday☐s total = 59
July 2014, Saturday☐s net total = 15, Sunday☐s total = 26 (Month to date)

Terry

Don't get me wrong.
Quote:
"there is no reason why a linear series pass regulator cannot be made to function to meet the original warm up and long term drift specs for any of the KW hybrids. Have to remember these radios were intended primarily for CW and SSB modes"

I agree with Your statement, even 100%. If time skill and will is there is no problem to have the rig in same shape and up to specification as it was when leaving factory.
If I had my 820 at a skilled shop for repair I would expect repair was to design configurations, unless told it was not possible.
It is a pleasure to see You have skill and pride to tell You do your repair to the original design.
Quote (mine):
"I have to agree, but there is no excuse to drift or jump around the band."

Sadly we have to admit all the skill in old components and circuits is getting harder to find (even with the help of internet) simply because many of the old school skilled people are not here any longer to tell.

Components stability issues that were common ham knowledge 30-40 years back is not that any longer. The younger hams don't know unless they are graduated engineers, simply because it is all digital and or SMD components populated board You don't repair.

My 2 cent were only to put in a way to line up a progress starting with documentation and trying to figure out what may be the cause or be able to ask the right question. The impression I have got so far is that most questions are more or less random, proving lack of homework.
All You skilled men deserve better than spending time to tell same story over and over again to us less skilled .
Repair on discrete component populated circuits is by no means a black art or magic,but a clear progress by understanding how it was intended to work and where it is at fault.

If an owner have 2 AF boards is it a quick solution to modify 1 board and figure out if it is at fault or the VFO.
I would never suggest to start messing up with the VFO unless other components/ boards are cleared first. If a person can't figure out the voltage issue and how to fix it I don't think he would be able to fix the VFO.
This last note is not for the old lads who have home-brewed radios, but more to the fact that these boat anchors are sold very cheaply and is therefore attractive to newcomers and others who have never had the opportunity to explore hybrid and radios built with discrete components.

I was lucky that I was allowed to repair some of the very last tube populated TV's, but I had to refresh my mind when I was looking at the final in the TS-820.
The mods on my 820 simply because I did not know the history of the rig, and I did not have

the time to do try on error on the voltage regulators.
I have not used it for any digi modes and probably never will, even I know the previous owner sold it cheap for a reason (he is all digital)

In 20 years will all receivers be SDR except from a few placed in radio museum's. The exceptions will be the few which are still able to run more or less in their original condition. To keep the interest running one needs to accept the modifications and upgrades as an opportunity to keep our spirits up.

My experience when using my 820 is that nobody would answer unless I was pretty close in freq (less than 100 Hz) and if I was jumping or transmitting 3.5KHz lower not a single one would reply, even less telling me I had some issue. Sure I should know better. Fingers crossed it will work as now where I get nice reports on signal (clean from splatter) and outstanding clear modulation.

Quote:
"Also, the digital display is constant source of problems and new technology has answers for that as well."

I would be pleased if You could provide a link to a true digital readout. Only I have seen are done by an offset for the IF.

I had no problem with your recommendation. I did my share of mods on many rigs over the years. Made lots of changes to HW-101s to improve them. Just wanted to explain to you why I always try to return customers radio to factory design config and why I advise new people how to do that.

Only recommendation I ever make about the VFO is to clean the rotor shaft wiper contact. It is a common source of VFO problems and easy to access and clean. There is a difference in VFO drift and VFO jumping or dropping out. Drift usually is not caused by corroded wiper contact. It is more commonly caused by the 9vdc supply. Drift can also be due to problem on the PC board. On rare occaisions one or more of the temperature compensating NPO capacitors will have changed values and sometimes just cleaning the board will help. So it is important to make sure you understand what issue the person is really experiencing. Over the years I have had a few VFOs that I just could not tame. I think in those instances the Huff and Puff would be way to go.

Yes we constantly repeat same things over and over again. I suspect may be due to the keyword search feature not being as user friendly as it could be. I have started to put some of the common questions on my website but much work to do there. Trouble shooting low RF drive is a frequent repeat question and I need to write up a good procedure on how to run the TX Level Diagrams and post on my site.

The key is stamped underneath "VIBRO KEYER" and "STANDARD."
There are 3 terminals opposite of the paddle. The middle one is only connected to the base itself, going nowhere. 2 metal strips connect the other 2 terminals to the left and right contacts on the key. (One long and one short.)
So it looks like I could set this up like a straight key, but to get the dits and dahs for left/right I'll need an electronic keyer. Right?

(Thanks for the replies guys!)

Hi Larry,

The Vibroplex "Keyer" you have is not a "Keyer", it's a "Paddle" that allow the operator to connect it to an "Electronic Keyer" such as an MFJ-407D or an old vacuum tube "Keyer" such as the Eico 717 or Hallicrafters HA-1 keyer.

The Eico and Hallicrafter's vacuum tube keyers use "Reed Relays" to key the transmitter. The MFJ-407D keyer uses a transistor to key the transmitter.

None of the Kenwood Hybrid transceiver have a built in electronic keyer. Therefore, if you use the Vibroplex paddle you will only be able to use it as a "straight key", you form all the dits and dahs yourself.

Last night I was working on the rig and was listening to all these stations booming away at me 59, near zero hiss. Two in particular I was trying very hard to get, one in Poland and the other in Austria. It was driving me nuts!! I could hear them like they were practically sitting in my lap, but here I was screaming away into my mic and to all intents and purposes, I wasn't there.

A few times during that 3 hours that I was on the air, I tried retuning various times, I retuned my antenna numerous times with the MFJ, trying to figure out what was wrong.

Eventually, out of desperation, I turned my CAR control up two notches (it was set at 12 o'clock) and the guy from Austria responded! Even then, signal was a 54 he said. There! Got my FIRST international contact! Boy, its taken awhile.

I wonder, was it the CAR control that did it? Or was it sheer luck?

I know, I know, I've got to do something with my homebrewed wire dipole. Right now, its strung from the trees, sloping from about 30 feet to about 10 feet, 16 feet on each leg, soldered directly to coax in the middle. Its good for only 20 m. I've got an Alpha Delta DXCC waiting in the wings. Gotta string that up quick before i lose my mind!

Changing carrier setting got first SSB DX for you?
It was just coincidence. Maybe band conditions changed when you did the change.
Turning up the CAR control only affects the power output on CW ! Doesn't do ANYTHING in the SSB modes.
The dipole for 20M works best at 60 ft high.

My radio is Ham Radio...CW is Real Radio

I could hear them like they were practically sitting in my lap, but here I was screaming away into my mic and to all intents and purposes, I wasn't there.

A few times during that 3 hours that I was on the air, I tried retuning various times, I retuned my antenna numerous times with the MFJ, trying to figure out what was wrong.

Eventually, out of desperation, I turned my CAR control up two notches (it was set at 12 o'clock) and the guy from Austria responded! Even then, signal was a 54 he said. There! Got my FIRST international contact! Boy, its taken awhile.

I wonder, was it the CAR control that did it? Or was it sheer luck?

I know, I know, I've got to do something with my homebrewed wire dipole. Right now, its strung from the trees, sloping from about 30 feet to about 10 feet, 16 feet on each leg, soldered directly to coax in the middle. Its good for only 20 m. I've got an Alpha Delta DXCC waiting in the wings. Gotta string that up quick before i lose my mind!

Mark,

"Screaming" into the microphone won't get you a contact. If anything it will get you complaints from other operators due to poor operating habits and possible splatter.

If you were still on 20 meter USB and you said you adjusted the CAR control and by doing so an Austrian station answered you, changing the CAR control setting in sideband mode had absolutely no affect on your transmit signal and power output level. The CAR control is "disabled" in sideband (USB or LSB). The CAR control is only enabled during TUNE and CW modes, never on sideband.

Working DX can be fun but it also can be a pain because a lot of DXers use high power but you're only running 100 watts and a dipole with no gain, you're going to have to work more to work DX. More than likely the reason the Austrian station answered you was because the noise level created by the many stations calling him, was significantly less and he finally heard you.

You also have to consider your antenna system. You hinted that you need to work on your antenna. If that's true than that would be the first place I would recommend you consider fixing.

Nothing to do with this change. NOT recommended, and besides it doesn't effect SSB at all. You specifically don't HAVE a carrier in side-band mode. It's called a 'suppressed carrier' signal for a reason. You tune OUT the carrier when you align the radio, as part of the normal adjustments.

> its strung from the trees, sloping from about 30 feet to about 10 feet,

Yowch. THERE is your problem. You're using a dipole meant to be at least a half-wavelength (a full wavelength or more is really the correct height) above ground at a height of less than one-quarter wavelength above ground on average, sloping to considerably less than a quarter-wavelength. It isn't going to work very well.

Almost ALL of your signal is going either straight UP, the rest is mostly going straight into the ground. You're getting a really broad side-lobe, and not much of anything useful in the main lobe of radiation.

Either direction, up or down, it's all wasted energy, doesn't matter WHAT the SWR meter says. That antenna isn't doing much of anything useful. Probably get some local contacts, 100 miles or less, but beyond that is going to be nigh-on to impossible.

What is happening is that the ANGLE OF RADIATION is changing. It goes closer to 90 degrees (measured from the plane of the ground, 90 being straight up). You want the radiation angle to be around 45 degrees.

The lower/closer to ground you get, the higher that angle goes. Anything lower than 0.3 wavelengths causes the angle to go VERY QUICKLY higher, the rate of change increases a lot.

Put your antenna into one of the free antenna modeling programs and vary the height above ground. Watch what happens at around one-fourth wavelength, three-tenths wavelength, half, and one full wavelength. (Above one wavelength there is VERY little useful difference.)

You might consider one of the vertical antennas for that band. They're not all that huge, and they get pretty good results for not a lot of space. AND several designs of vertical don't have to be (shouldn't be) really high off the ground. You use radial wires buried in the soil around the base of the antenna, cut to resonate at the frequency of interest, to get the signal out of the wire and into the sky. In simple terms and within reason, the more ground radials you have, the better these sorts of antenna work.

There are tons of do-it-yourself plans for inexpensive antennas on the internet. Multiband trapped verticals are easy to build. (Horizontal ones aren't any harder. They just need more space side to side....)

Mark,

If I may recommend a source of single sideband study it is the ARRL book titled "Single SideBand for the Radio Amateur". You can find this book on eBay and at hamfest. A person cannot understand how sideband works if they have no idea how sideband is processed in a SSB transceiver.

Another area one might consider is studying about antennas using the ARRL Antenna Handbook. I also recommend the older editions of the ARRL Handbook for antennas, less "filler fluff" contained in the older editions.

Mark:

KW design engineers spent money to design speech processors for the KW hybrids radios and depending on which model you have it can be a very effective RF processor. The TS-820 and TS-830 are particular effective if aligned properly. Often using it and using it correctly as described in the operator instruction manual can help you break those DX pile ups running barefoot with a modest antenna installation. Really fun when you can do that. I dont use processing with state side contacts but will use it if I am chasing some DX.

Mark,
The advice given is correct, Car had no effect! What catches my eye is your antenna! 16X2=32ft? It is resonant at 14.625! Add 6 inches to each side, get the SWR closer to flat at the frequency area you are trying to work, and bypass the tuner. Good luck and good DX.
It's a good distance from Vancouver to So. Texas maybe we'll work on 20m:>D

And here we have one of the other things about antennae that seems to be a forgotten bit of lore. SWR is NOT the be-all and end-all of antenna tuning.

Yes, resonant length and impedance matching are important, I will NEVER be accused of saying otherwise. But more important for actually getting the antenna to do what you want it to do is understanding things like RADIATION ANGLE and SIDE-LOBE PROPAGATION. Height above ground is extremely important for bog-standard center-fed dipoles and changing the radiation angle of the signal.

You may be getting a coupling and impedance match of 1.1 to 1 as far as the SWR is concerned, but at twenty meters SSB, and only an average of 20 or so feet off the ground, you're getting a radiation angle of about 85 degrees, or just about STRAIGHT UP.

The signal, IF it bounces off of the ionosphere at all (instead of punching right through and being lost in space, headed for Beta Hydrae or something), at that angle will be reflected almost right back into your back yard.

Anything left over is either eaten by the earth ground, or lost in a side lobe which also doesn't get much further than the next block over, and which is headed in the direction a quarter-turn from where you hope to be sending anyway.

You want a LOW angle to reach for those far-away stations. Otherwise, if you want to get past the neighbour's fence posts, you're stuck waiting for a rare phenomenon like an ionic duct to form, and that is sheer luck and nothing you can count on.

SWR is only ONE piece of the antenna puzzle. And the smallest one at that, for my tuppence.

Topic: 49398 Message: 49398

Hi All,

new to the group and thought I would pop bye and say hello.

I currently own a TS-530SP and a TS-830S which arrived this morning as a second user purchase. The TS-530SP was my first rig when getting my A class liec back in 1982. I have a number of Kenwood radios including 2 x TS-930s a TS-570S and a TS-590S.

One minor problem I have with the TS-830S is that while it tunes up fine on the CW-W and CW-N positions I cannot get the unit to dip or peak in the tune position. In the tune position I can switch to ALC and peak the Drive with no problem and the bias sets to 60 mA with no problem but in Tune I get nothing on Ip or RF on the meter. The rig works fine once tuned in the CW mode and I get a good 100 watts out on CW and SSB.

Any one any idea's not sure if it is in the PSU on the 100 volt rail in tune as yet and the circuit diagram takes a little following around those points as it is so Small.

Thanks,

Peter G4NTN

Peter,

You said the following:

"/*One minor problem I have with the TS-830S is that while it tunes up fine on the CW-W and CW-N positions I cannot get the unit to dip or peak in the tune position. In the tune position I can switch to ALC and peak the Drive with no problem and the bias sets to 60 mA with no problem but in Tune I get nothing on Ip or RF on the meter. The rig works fine once tuned in the CW mode and I get a good 100 watts out on CW and SSB.*/"

I recommend you check resistors R15 and R16, both are 56K 1/2 watt, that are on the TS-830 Rectifier Unit board. These resistors are used in TUNE mode to reduce the 6146 final tube screen voltage. If their values change significantly, you can experience the symptoms, in TUNE mode, you are experiencing. If one or both of the resistors are found to have changed resistance by a significant value, replace both resistors with new 56K 1/2 watt resistors.

Do you have the operator and service manuals for the TS-830? If not you can download them, including a TS-830 "high resolution" schematic on my website:

Welcome Peter. This is a great group, and very active as well.

One thing that will greatly help the really experienced people here - if you can list your currently available test equipment, and your level of expertise troubleshooting these fine rigs. There is available a larger and easier to read schematic; take a look in this group's archives. If not, I'm sure someone will provide the WEB address for it.

Good luck with it.

Hi Terry.
That's an interesting thought indeed. I attended my local club's informal meeting last night and learnt to cut, strip and solder my first PL-259 to LM-400 line. That's how new I am. It was an educational session, and like many of the other respondents to this thread, the main consensus was that the antenna just wasn't doing it for DX. Anyways, I put up an Alpha-Delta DX-CC last night. Its set up as an inverted V, with the centre about 30 feet up. It's the highest I can go at the moment, until I figure out how to trim my trees myself. Local tree trimmers want $600 for the job.

The wires are either touching or very close to leaves and branches. Still, I managed to hear some loud booming conversations on 40, as well as 80 metres. I made one contact, in Lithuania on 20 metres. Pretty happy with myself, as I spoke in a totally normal voice, keeping my eye on the ALC to make sure it didn't go over the scale.

Hopefully with the new antenna, and once I've trimmed the trees to allow for me to pull the apex higher, I might get better DX.

The Kenwood is great. The internal speaker is great. maybe a tad loud. If I use the RIT feature, I can tune right into conversations very well. However, the manual says to not leave it in RIT. So I've switched if off to transmit.

Gary,

Yes and no. Ken Kemski (k4eaa) has large format "level diagrams" for the 520 series. These are most useful for troubleshooting. You can have the schematic scanned and enlarged at most major print shops....Office Max..FedEx Office...and others...$10-20 bux depending on size and detail.

Hello all. I am Gary, WS5J Located just South West of Fort Worth, Tx. I was lucky enough to find a real nice TS-830S in the factory box and loaded with every filter slot full for an excellent price at the last Fort Worth Ham Fest. Inside the box I also found a perfect condition MC-50 mic that had been disassembled and fit inside the box. This radio had not been powered up in close to 30 years, so to be on the side of caution I replaced the HV Caps and as the relays were a little "iffy" I replaced them with some solid state relays. It has been working perfectly and I really do enjoy playing with it. My main station is a Yeasu FT-2000 with the DMU-2000 and I am using both the MD-200 microphone and the Heil ProSet Plus head set. With a nice home brew amp, I am putting 1 KW to my antenna system which features a 4 element 6 band cubical quad at 80 feet high also 100% home brewed.. Hope to work you all on the bands someday. 73 - Gary Woods WS5J

Gary,

I should also add that Ken Kemski's(k4eaa) diagrams are FREE to download...and IF you have a good quality original schematic..it can be scanned and enlarged greatly to make it easier on the ol' peepers by the aforementioned stores

Gary,

Welcome aboard. Finding an 830S, full filtered, with original box & an MC-50, was quite a score. Hope the XYL appreciates it....hihi.

You may want to partake in the Kenwood Hybrid Net. You can go to: wb4hfn "dot com" for net times and freqs.

Also, you may want to go to the "home page" of this group and look thorough the "files" section." Lots of good info

Hello everyone,

I'm the guy with the new switch handles on eBay, but had taken the listing offline last May.

I am restocked and have reposted the eBay listing for sets of five handles, your choice of colors - usually all five black, or four black plus one gray.

USPS Priority Mail shipping is free to you. Mention this group and I'll reduce the cost by $5 per set of five handles. You should be able to search by 'Kenwood Switch Handles' and you'll find the listing.

For those interested in single units - either gray or black - I should have that listing updated and reposted shortly.

Many thanks to the Group!

Terry,

Thanks for the positive review on these switch handles.

I've gotten listings back up on EBAY for both sets of five and individual handles in both gray and black.

You can find the listings by just searching on Kenwood Switch Handles.

Best Regards,

John KF7QGU

In my defense I do use JB-Weld on the paddles that I sell BUT only in the small keeper tabs that tend to crack... If a paddle has a keeper tab broken off I toss it...

Bob

No defense needed. I wasnt pointing a finger at you.

I simply said make sure not buying a JB Weld repaired paddle unless that is OK with you and in my 2nd sentence I state they are a lot cheaper than buying NOS paddles.

I see nothing wrong with strengthening a paddle that has a crack so crack doesnt propagate, but I would not want to buy one that had broken off tab glued back in place. You have made it clear you dont do that or sell that kind of paddle. Didnt mean to infer that you did. In fact wasnt thinking of you. I have had more than one rig on the bench with epoxy repaired paddles and I assume the owner did it?

Just trying to make sure that our member who buy from any source are informed buyers. Not picking on you. I have had nothing but superior service from you and regularly steer people to you. We are all fortunate that you provide this service to us.

Peter,

I have a video on my website, see link below, that talks about a similar series circuit, how to calculate current, and the voltage drop across the first resistor in the series string (9.9K) then subtract the voltage drop from the source voltage to calculate the voltage at the junction of the 9.9K and 21.8K resistor, same way as the R15 and R16 series circuit works. This video can also be applied to the 520 and 820 HV Unit series circuit, R5 and R6, both 56K 1/2 watt. That circuit works the same way as the video does.

I have created a page on my website and uploaded a few Elementary Electronic magazine issues that contain several excellent articles on Basic Electronics for those members who want to learn.

Electronic Magazines | W5RKL http://w5rkl.com/old-electronic-magazines/

Electronic Magazines | W5RKL http://w5rkl.com/old-electronic-magazines/ Elementary Electronics Spring 1965 Spring Summer 1969

View on w5rkl.com http://w5rkl.com/old-electronic-magazines/
Preview by Yahoo

I intend on adding additional magazines that contain basic electronic articles for those who are interested in learning.

There have been a number of members who have indicated they want to learn. If you still want to learn you will have to devote some time to reading articles on theory. I mean no disrespect but if those who have stated they want to learn BUT can't or won't devote time to study, at least an hour a day, then don't expect to learn anything. If you can only devote a couple hours on weekends, that's better than nothing. Don't expect to learn it overnight, over a weekend, or even after 6 months or more.

Peter

I assume you are reporting that you have correct RF drive voltage level at the output of the TX Mixer at MD (approx 2 rms rf volts) and have very low RF drive voltage at the Plate of the Driver tube at DP or DRV. Is that what you are saying?

Pin 2 of the Driver tube is the Control Grid of the tube. This pin sees Cut-off bias (-37vdc) in receive mode and Operating bias (+ 0.30vdc) in transmit mode. If the bias isnt switching from Cut off to Operating the tube wont turn on. You can also prove that by measuring the cathode voltage in Tx mode. It should switch from very low value in Rx to approx 4.0vdc in Tx mode. Need cathode current to get IR drop across the resistor string in the cathode circuit.

I dont know about your ability to take DC voltage readings. Some folks really struggle with this key task and commonly report flawed readings. No offense intended, but in order to help anyone we must have factual input. You have to be familiar with your DMM or what ever voltmeter you are using and how to measure low values of dc voltage. I would repeat your measurements at Pin 2 to be 100% certain that Pin 2 doesnt have a small positive dc voltage in Tx mode.

Also, why didnt you measure Driver tube screen grid voltage in Tx mode when you were there measuring it in Rx mode? That was the time. If worried just flip the SG switch off and then Flip to Send and should see that 250vdc drop to around 200vdc. Very likely that your screen grid voltage is ok. Common failure is in the divider resistors that supply it and if you have 250vdc in Rx mode most likely will have screen grid voltage in Tx mode.

If you do not have small positive voltage on the Driver tube control grid Pin 2 come back and we will have to talk about Q6 bias switch circuit.

Perhaps first step would be cleaning the contacts of the Aux Relay (located under the Vox board) before trouble shooting Q6 circuit.

Terry K9TW.

49427. LMO and VFO instability

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-07-28 14:26:56 UTC
From: Mike W5RKL
Topic: 49427 Message: 49427

I made and uploaded a video that covers the Heathkit TRW LMO (VFO) inside view. The purpose of the video is to show the inside view, the multiple tab washers on the LMO tuning shaft and how to clean them when they stick (sticky tab washer prevent tuning the LMO from one end of the dial to the other, only partial tuning is achieved). The video also shows where "instability" in LMO tuning can occur when dirt/corrosion collects at the LMO variable capacitor shaft and frame connection.

Although the video is about the Heathkit TRW LMO (VFO), the same variable capacitor shaft to frame connection exists in the KW Hybrid internal and external analog VFOs and the same cleaning process is required to fix instability tuning of the KW hybrid VFO.

The video is found on my website

www.w5rkl.com

on the "Electronic Video" page. Click on the video page link then scroll down to the bottom of the video page and click on "TRW LMO Inside View" link.

"LMO" stands for "Linear Master Oscillator" which is the "VFO" built by TRW and used in the Heathkit SB-100 and SB-101 transceivers, the SB-300 and SB-301 receivers, and the SB-400 and SB-401 transmitters. The LMO tunes the same 5.500Mhz to 5.000Mhz frequency ranges as the VFO in the TS-520 and TS-820 does. The HW-100, HW-101, SB-100, SB-101, and SB-102 are very close to the TS-520 operation. The same basic conversion and mixing process takes place in the Heathkit transceivers as it does in the Kenwood TS-520 transceiver.

You do not have to remove the VFO in the Kenwood Hybrids to fix VFO tuning instability due to dirty VFO capacitor to frame fork connection. When I say you have to remove the LMO to fix this problem, that applies ONLY to the Heathkit LMO, NOT the Kenwood Hybrid VFO! I should have said that in my initial posting.

Hi Mike:

As another source of a very good picture of the TS820/TS520 VFO air variable rotor shaft wiper contact can go to Gordon N6WK website and search under Kenwood Hybrid files under TS-820 VFO Repair and scan thru the pictures and there is a very good shot of the rectangular side cover pivoted open on one of the two retaining screws and a nice close up view of the "forked wiper contact" and the rotor travel stop screw as well.

This is the same air variable capacitor (very high quality unit) used in the TS520, TS520S VFOs. The air variable on the TS530 and TS830 is much smaller and the wiper contact is no where near as substantial.

Sure glad someone put Gordons stuff back on line.

Terry K9TW

Hi Terry,

I didn't know there were pictures of the KW hybrid VFOs on Gordon, N6WK website. I knew someone had taken over Gordon's website but didn't really look at it so one learns something new everyday.

I have to put the VFO in my KW R599 receiver, it "warbles" when tapping on the cabinet. Other than that the receiver works great.

A ham on the Yeahoo Heathkit group had an SB-401 transmitter LMO physical tuning problem, the LMO would only tune about 150Khz, some of the tab washers were stuck and would not rotate freely. I told him the LMO should be removed from the transmitter to fix it but he wanted to know if it's possible to leave the LMO in the transmitter to fix the problem. I said he could do but it would be a lot more difficult fixing this problem by leaving the LMO in the transmitter so I made a video showing what the problem was and how to fix it properly. Since I had the LMO front and bottom panel, an "L" shape panel, already removed I figured why not show where the "Fork to shaft" connection is on a variable capacitor, something that some members may not understand or have ever seen before.

Hi Jim,

I heard some guys from Texas just last night. They were ragchewing and I didn't want to bother them. I've even heard them as far as Florida. Last night, I heard a guy from Slovenia, Poland and Japan. They couldn't hear me though. I'm pretty sure we'll meet on the air one day Jim.

Just so you know, I put up an Alpha Delta DX-CC antenna since I last posted to the group. All the stuff I heard was using that. Last night though, the bands seems to be dead, with very few conversations, but lots of noise. I did hear some very very strong signals from Texas though, on 40 meters. There was one group, that near the beginning of the band that were talking about cars. One fella was so loud, that when he spoke I nearly spilled the wine I was drinking! I had to keep adjusting the volume just for whenever that guy spoke.

So right now, all is good in my shack. I just think conditions are not too good now.

Hope to talk to you soon, cheers!

Topic: 49432 Message: 49432

my TS830s was working fine, but then all of a sudden no ALC indications, and when i wiggle the driver tube, RX goes almost dead.

no ALC on xmit on any band all of a sudden. Bandswitch cleaned already not likely there..

pulled out the driver tube, required super-human strength, and found there is some foreign substance that actually looks like super glue in a couple of pins. Tried to clean/deoxit etc. still have to wiggle tube to wake up receiver (this may be separate non-associated issue?).

want to remove the board, and replace the socket. How/what is the best way to remove/replace the RF board? looks like a royal PITA. person i bought it from said it had RY1 replaced by KW (but i have k4eaa's replacement if needed).

hopefully one of these suckers works -
http://angela.com/ninepinnovaltubesocketsandaccessories.aspx
http://angela.com/ninepinnovaltubesocketsandaccessories.aspx

what is the most common failure for any ALC indication - best place to look first?

i have a fair complement of tools (Tek oscope, HP sig gens, counters, etc).

-bob, w9zv

Bob,

Removal of the 830S RF board is easier than the 820!!

You will need: soldering gun/pencil, phillips screwdriver, needle nose pliers, long allen wrench(to fit the set screws on bandswitch coupler).

With rig OFF and unplugged...remove top cover, remove digital display board, remove driver tube. Remove final amp cover...check for voltage on plate choke...before you go any further!!!
No volts??? ..remove front tube. Make sure that your band switch ...etc... keeps proper orientation...turn bandswitch to "1.5"...loosen the front most set screw of the coupler....turn bandswitch to "10"...(10Mhz...not 10meters.) There may be small spring wires on the shaft...remove...withdraw shaft..pay attention to orientation of everything! Remove all connectors and ...don't forget the VCO cable...from the RF board...unsolder the 2 white wires...going to the final amp cage. Loosen the collar and the coupler to the "Drive" control shaft...right behind the upper right front of the chassis. Remove the 7 phillips screws holding the RF board in place. I find it easier to now turn rig upside down..to get to the blue wire going to the "drive" post on the final amp board. I remove it from the RF board. The board should now come out very easily...if not...you forgot something. Usually takes about 30 minutes. Just go slow and document the position of the bandswitch wafers...and the shaft orientation!

Be very careful when removing the "molex" connectors! I spritz them with a bit of DeoxIT before I try and remove them...has helped me numerous times. You can induce faults that will really make your day!! Get some very good magnification and bright light...inspect board.

I doubt the driver tube issue is causing the RX issue.

Is your lack of ALC in "tune mode" or during regular operation? First suspect is a poor/failing or failed driver tube...or socket/soldering to board.

You can go to this groups "home page"...click on "conversations" by the left lower corner of the station picture....you'll be taken to another screen...in the box at the top...enter your criteria...say for example: "TS-830S no ALC in transmit." This will give you LOTS of info to go through...the "Files" section has lots of good stuff too!

Mike:

Yes that was a good idea to take that opportunity to show folks what a wiper looks like.

I remember the LMO and how happy I was when I got my first one and had 1khz readout for the first time. I married up a SB-640 vfo with my HW-101. There was room on the face of the SB640 to add a centralab ceramic selector switch and I mounted a relay on the side of the PA cage and was good to go. I think I used dry transfer lettering for the switch and bought a heathkit knob and it looked like it belonged. Worked like a champ.

Of course all the various wipers in the different model Hybrids are slightly different. I clean the wipers on every air variable when I work on any Hybrid. I dont think some people realize there are 4 wipers on the 3-gang Plate Loading cap and I see them that are a nice green copper oxide coated. The VC-1, VC-2 and VC-3 Drive capacitor wipers are also usually corroded.

I was listening on 40 meters while working the other day and heard a guy tell the other fellow to put a screwdriver in and try to bend the wiper to give it more contact pressure. I had a vision of his RF bench with a ball peen hammer, pipe wrench, and vise-grips hanging there!

Topic: 49432 Message: 49435

Bob,

When you have RF board out as described by Joe, have a good look under magnification and lighting, at all of the molex connector soldering joints and wafer switches foil tabs. If they are cracked then remove all solder, lightly sand and then resolder. Almost impossible to just reflow solder and get good connection. Dont over heat the foil tabs as they can lift easily

Based on your description, more than likely the socket tabs have poor soldering from factory.

You may want to consider giving your PA a blow out with compressed air and lube fan, it is highly recommended doing this yearly

Please report back on your findings as it does help some of the newer members

Bob

Rather than pull the RF board you may want to access the driver tube socket tab soldering by removing the RF board access panel by folding over the AF board. This gives you access to the foil side of the board. You will be able to see if the tube socket tab soldering is cracked (pretty common due to repeated pushing and pulling of the Driver tube). Can re-solder the tube socket tabs from the bottom side. This may fix your loss of ALC indication and loss of receive.

The likely reason that you are losing receive when wiggling the Driver tube is due to losing the cut-off bias to Pin 2 of the Driver tube. When that happens tube will conduct and there will be cathode current. That current will cause IR drop across the cathode resistors. You can see from schematic study that there is a diode protection scheme that gets its forward bias from cathode resistor divider tap. When the Driver tube is turned on you dont want any transmit RF to enter the front end of the radio and damage Q1 RF amp. KW engineers designed the D2 protection diode circuit to shunt strong RF that appears at Gate 1 of Q1 to ground to protect the dual gate mosfet from its own transmit RF. Some folks think D2 is an ESD protection device and that is not correct. It takes Driver tube cathode current flow to forward bias D2.

If you turn the heaters off and wiggle the Driver tube do you still lose receive? If so, then my thought about loss of cutoff bias voltage at Pin 2 isnt valid.

Of course pulling the board allows you to inspect all the molex pin soldering.

Topic: 49437 Message: 49437

Hello Group,
I need to replace a diode in the power supply for my TS-511S. It looks to have turned to powder and crumbled at the touch of my plastic adjustment tool. I may even have caused it to fail. I didn't think I touched that hard. The old no. is S-1.5-08. I can find no info on it. Does anyone own and maintain a TS-511S other than me? I could use some advice before I pick any. This is a 900 Vdc supply.
This supply has never been touched before. All original components.
Thanks in Advance,
73, Don K5HFG

Hello Don,

If the diodes you are referring to are the 4 HV diodes in the PS-510 power supply, you can replace all 4 of them with 1N4007 diodes which quite often have been available at Radio Shack. If not then Mouse sells them.

Before you replace the diodes you need to check the supply thoroughly to ensure there are no other components that caused the diodes to disintegrate as you said. Diodes that crumble as you said they did indicate a high current demand was placed on the power supply. I also would check the fuse to ensure it's the correct current rated fuse. The only schematic I have of the power supply is a PS-510 schematic where the power transformer primary windings are 235/250VAC, no 120VAC primary windings. The fuse is rated at 8 amps at 235VAC. You also need to check the power transformer's HV windings for shorts to the core or if the transformer smells of burnt/overheated insulation.

You should also check the final amplifier for failed components that could result in a high current demand placed on the PS-510 HV supply. If an arc occurred in one or both of the final tubes between the plate and the beam forming element then that arc would be the same as grounding the HV supply output directly to the chassis resulting in high current to flow in the HV supply. Normally this would blow the fuse so you need to check the power supply fuse to ensure it's the correct rated fuse. I've seen 15 amp fuses be used in place of a 3/4 amp fuse. Needless to say the power transformer was toast when the supply filter capacitor shorted to ground.

Could you pretty please DECODE that subject line? Something about a radio that was in a flooded room? Water in your S-meter?

Colour me confused.

Did the radio work at any point since you had it in your possession?

Did you clean the band switch and other switches in there? If there was anything to this water problem, there is going to be a lot of cleaning and corrosion removal required before this thing will work. If it was under water, even 1/3 of the way up the S-meter, whatever, I wouldn't plug it in at all until the cleaning was completed.

More information, please. What kind of tools do you have other than an oscilloscope and a signal generator? Do you have a frequency counter, a vacuum-tube voltmeter, and an RF-Probe to go with it? (You can make the probe for pocket change, or less if your junk box runs to some small-signal diodes, a resistor, and a small ceramic disc cap.)

The VTVM is not just for glitz or bragging rights. Those meters have around a 10 or 11 meg ohm input impedance, rather than the ONE meg ohm or less input impedance of the run of the mill digital or even FET multimeter most benches have on hand. This allows you to get much more accurate reading from circuits, because the meter doesn't load the circuit under test and change the readings.

Also, how rusty? Do you still remember how to handle yourself around B+ voltages? There's about 900 VDC waiting to eat you for lunch at the top of those final output tubes, and various other places inside that chassis. Do you have a 'zap stick' or 'chicken stick' to discharge the electrolytics in the finals power supply? (And you're not so rusty that you think throwing a big spark with just a bare wire and no resistance in line with it will make that cap safe, are you? The electrolyte CAN re-charge after a high-amperage discharge, which is why a chicken-stick has a resistor in the line and you leave it on there for a bit to allow things to gain a new and low-potential equilibrium.)

We truly do need more information, as well as some translation of that subject line. Also, do you have the schematics, service, and operator's manuals for your rig? They're all available for download, for free. Including some very high resolution ones that can be printed out "poster sized" and studied or marked up with ease. (My old eyes need those bigger drawings, else I can't make much of the circuits, too small to

see the details.)

Expertise there is in abundance on this list, and we try (most if not all of us anyway) to use plenty of patience. You've come to the right place if you're in need of help fixing your radio.

Topic: 49438 Message: 49443

The input impedance of a digital volt/multi meters (DVM/DMM) can be found in the meter's manual. I use 3 different makes of digital multi meters and they all have a "10 meg" input impedance in AC and DC ranges. The meter probe resistance must also be considered when can easily be 1 ohm of resistance.

A typical VTVM will have a "1 meg" input impedance in all AC voltage measuring settings and a "10 meg" input impedance in DC voltage measuring settings. The "11 meg" impedance is based on the addition of a "1 meg" probe that's used in all DC voltage setting. Adding the 1 meg probe resistance to the 10 meg input make the VTVM's DC input 11 meg. The typical VTVM probe is quite often a "universal" probe that contains a switch that removes the 1 meg resistor when measuring AC voltage but puts the 1 meg resistor back in the probe when measuring DC voltage. Unfortunately, not all VTVMs sold on eBay or elsewhere have the correct probe so the buyer must make them. I use thin diameter hollow plastic probes (RED for positive BLACK for negative) with a 1 meg resistor inside the RED probe. These hollow plastic probes are becoming harder to fine. I also change the typical "screw on" single conductor connector on the front panel of VTVMs to a "BNC" female socket, works much better.

One also must understand that using a DVM/DMM or VTVM when measuring voltages, will have an affect on the circuit the meter is connected to. For example, using a 11 meg ohm VTVM, even with the correct 1 meg probe, will drag down an AGC/ALC buss.

Any equipment that has been exposed to water, i.e., sitting in water in a basement or other location, for any length of time, should be thoroughly cleaned and set out to dry for at least a minimum of 2 days followed by a thorough visual inspection looking for any foreign matter that was missed and any damage that may have occurred, before even considering apply power!

Understanding and following standard safety precautions when working around any level of AC or DC voltage is a must for ALL hams and people working in the electrical industry! It's not the voltage that kills you, it's the CURRENT!! A DC voltage as low as 40VDC at 200ma can KILL you!! The link below contains discussions about electricity and how it affects YOU.

https://www.physics.ohio-state.edu/~p616/safety/fatal_current.html

Don't become complacent when working around electricity, there are plenty of people/hams who are now 6 feet under who for reasons unknown, became complacent when working around live AC and DC circuits!!

Mike,
Thanks for the reply. This rig is ancient and I knew at some point I would have to do something about the HV supply. I do not operate it very much but do occasionaly operate CW on 40 and 80. I began to notice some fluctuation in the output so I took a look in the final cage and found no problems. A few nites ago I noticed the output slowly fall back again so I got the manual out and looked at the trouble shooting section and it says to check the diodes.
I admit that I may have tugged on the one a bit too aggresively. It did seem to disintegrate rather easily. Anyway I have the PS511s schematic and will add the replacement diodes to the component list after I read their data sheet. I was not sure and thought I would ask for some advice. Between you and Terry I figured I would get some good info. This old girl sounds so mellow on SSB I like to just listen on 80 while I work at the bench. And the smell, it takes me back to better days. Remember those? By the way, I caught the filter caps just in time. After replacing them I poked around the bulge in the bottom and they caved in. I thought I could see some cracks under the magnifying glass and sure enough. How is that for luck? Not bad life for originals.

As Mike directs read the DMM manual specs. Remember that some DMMs input impedance is range dependent. You may think it is a 10 meg meter when it is not. It can be as low as 1 meg ohm on some ranges (especially the lower ranges) The Harbor Freight $9.99 DMM runs close to 900k input impedance and better for electrical work and not electronic work. Electricians need low Z meters to verify circuits are truly de-energized before they barehand touch.

If you dont have the manual couple of ways you can check the meter:

1. Try to measure the AGC bus and see what happens. A 2 meg meter will drive the S meter up scale and reduce the gain significantly. The 3.3vdc will measure around 1.3vdc and S-meter will read 10 over or higher.

2. Take the reading that you want to measure and then insert a 100k resistor in series with the plus lead and take the reading again and see if reading is significantly different. If it is the impedance of your meter is too low for what you are trying to measure. You can insert a 1 meg resistor in series and take the readings. Will be about 10% low but wont affect the circuit as much.

Easy to measure your meters input Z:
1. Use a constant current source like a fresh D cell battery
2. Measure the battery voltage with the DMM
3. Insert 20 meg pot in series with plus lead of meter and connect back across the battery. Adjust the pot for 1/2 of voltage that you measured in Step 2. If you dont have a 20 meg pot can use a combo of fixed resistors and a different pot.
4. Remove the pot after adjusting for 1/2 voltage and measure the resistance of the pot. This is the input Z of the meter on that range. Hopefully the resistance will read around 10 to 11 meg ohm.
5. Best to do this test on the meter range you intend to use to measure voltages in the rig.

Hi All.

While I am not entirely new to the Kenwood hybrids, having owned a TS-820S and TS-830S in the past, I have reentered the fray with the recent purchase of a TS-520SE. It is quite clean and the receiver works very well. However, it seems to have a bug in the transmit chain that causes it to not give any ALC indication when attempting to set the drive control that I'll need to chase down as I go through the basic alignment in the days ahead (it may be a loosened connector from shipping as I got it to tune up once after reseating the 12BY7A but then an hour later it was unresponsive again).

As I tend to listen much more than transmit, I'm a bit concerned about the tube filaments be powered all the time. Is my concern unwarranted even though the heater switch was included with the 530/830 models? I knew this was unique to the SE before I bought it, so no surprise there. Has anyone worked up a mod to switch the filament power as with the other models? I'm guessing a separate switch would be in order if it is even possible to do this.

My motivation for acquiring the radio is that it fulfills my idea of "vintage". In early 1981 I had just gotten interested in amateur radio and ordered "Tune in the World with Ham Radio" from ARRL and found the prominent TS520SE advertisement. I did not go that route as I wanted the WARC bands and jumped into Heathkits for a while and then the '830 in 1986. In 1995 I picked up the '820 as a second radio but traded it in 1999 for an FT-890 which allowed me to run HF mobile for the first time. About ten years ago I sold the '830 to a local as I wasn't using it and he doesn't wish to part with it. I chose to go back to something I dreamed about before I was ever licensed. My plan is to use this as a "vintage" radio for things like Straight Key Night and so on.

Hello Nate,

My first Kenwood hybrid was a TS-520SE and a DG-5. Great radio, worked tons of RTTY in the early 80s using a Flesher TU170 TU, Teletype Corporation KSR as well as a Radio Shack TRS-80 Model 1 computer with "Cassette Tape" load software and a Macrotronics interface.

You said your TS-520SE lacks ALC. I assume that is during TUNE mode transmitter DRIVE tune up adjustment. If this is true then I suspect resistors R5 and/or R6 on the HV Unit have increased resistance which is causing a much lower level of screen voltage to the 6146 final tubes than normal TUNE mode level.

Check R5 and R6, they are both 56K 1/2 watt resistors.

Mike,
I do not have them on PDF format but what I do have are some very readable copies. I will drop them in the mail. I tried to get the 511S schematic enlarged but it did not turn out very professional. I will send what I have and if not good enough you can borrow my manual and copy what you want. I will get this in the mail this week and let you decide if it is good enough.
Regards,
Don K5HFG

I ran packet, PacTOR and RTTY on my '830 in the late '80s and early '90s
using a KAM. I tried AMTOR once or twice but I was afraid the relay
would pound itself to dust! I found the finals ran much cooler after I
neutralized them, particularly on RTTY.

My first computer was a TRS-80 Color Computer 2, cassette tape and all.
Within a few years I had a disk drive, etc. I like going back a bit in
time with the old radios, but the old computers can stay there!

Yes, this is in the TUNE mode when trying to peak the DRIVE using the
ALC meter scale. I will check those resistors. Thanks for the tip,
Mike.

Steve:

No shame in swapping boards. Often the fastest and easiest thing you can do to return a radio to service. It is what the big boys do as time is money.

Suggest you do Step 9 in Service Manual if you have not already with the "new" board. Hopefully you took a real good look at the molex connector pin soldering. I also like to apply a little deoxit to the LSB and USB trimmer caps TC-2 and TC-3 and exercise them before setting the SSB frequency response. That is typically about all you need to do with a PLL board swap other than setting the 10mhz reference clock.

Hang on to the PLL board as they are worth around $50 to $60 dollars. Even if you never align it you may need to harvest parts from it some day.

I am sorry for any confusion. Although a member of this group for many years only viewed it never posted to it.

This is the whole story. I am a dedicated hybrid user. Bought my first Ts820s in 1978. After it was stolen I replaced it on Ebay then bought a second some years ago when the price looked good as a spare. Both worked fine before the water except for occasional DG1 issues common to most TS820s. About a year ago I bought a 756Pro. I was so taken by the spectrum analyzer that the two Kenwood went to storage. But foolishly storage was next to my operating
desk on the floor handle up. We had one enormous rain in December. Both Kenwood radios were sitting in 3 inches of water (remember stored suitcase
style handle up). This places the IntFreq (IF Board) closest to the floor. The height of the rain water in the rigs looked to come up to about 30% of the S Meter.

OK, Now for what I did. Removed both IF Board and soaked in Dish Soap water mixture for an hour then rinsed in water. Then board were dried with hair dryer and sprayed with DeOxit as recommended by Ken K4EEA.

One rig finally came back to life. It is as good a new.

The other radio has no audio. With earphone an increasing hiss is heard with increasing gain. The lights are on and the DG! works. The meter survived. I can trouble shoot with my scope which is a calibrated tektronix and has a high inpit impedance.

I have 2 blown up (24X36) schematics and all the manuals, mods, bulletins etc. I am experienced working with high voltages. I am not familiar with the layout by heart because I have never been required to troubleshoot a TS820s before.

So, when you suggest checking the bus voltage of something, please tell me where things are ocated until I get the hang of the rig. Like an old am radio,
I know what the five tubes do and how they do it and know the schematic in a general way in my head.

But the Kenwood is another level of complexity, so spoon feed me on where to check voltages and which lines do what to get a sense of what is working.

My Simpson 260 is too low in impedance. Some new small digital meters that I picked up, I'll check for the input impedance on the web. If not I'll find a pot.

Please tell me where to begin and generally how voltage and signal lines are identified.

The 7 pin shorting plug is in. The send switch is off. Only rcvr is on for now, transmit power (lower right) is off .

I appreciate your time and patience and look forward to any guidance you could provide.

Thanks,
Arnie WB2ABM

Arnie

When you say transmit power on lower right is off I think you mean the filament voltage is off (Heaters).

My guess is that the water didnt hurt the rig that has audio problem. I think you need to carefully pull the molex connectors off that IF board and clean with deoxit and reseat them for starters. Two events occurred. 1. Water immersion and 2. Removed the IF board and cleaned and dried it. My guess is the issue is related to the pulling and cleaning and re-installing of that IF board.

If you have no signal generator can use the Marker signal to trace the RIF with your O-scope to see if losing it. Can drive the AF board with any source of audio to see if it is functioning (tape recorder, MP-3 player, Lap top sound card etc). Even a clip lead at wiper of AF gain pot and a finger applied should produce a nice hum in the speaker.

Topic: 49438 Message: 49456

Arnie,

I agree with Terry's suggestions and comments. If I may add a comment or two to Terry's response.

1. The TS-820 does not have 5 tubes, only 3. A 12BY7/A driver and a pair of 6146Bs or Japanese S2001A equivalents.

2. The HEATER switch you refer to as the "Transmit Power", when set to ON, applies 12VAC to the driver and the final tubes (the 6146B filaments are wired in series). Naturally the opposite occurs when the HEATER switch is set to OFF.

3. The jumper plug and socket on the rear panel you referred to as being a "7 pin" socket is actually a 9 pin socket, it's the Remote VFO socket. The jumper plug has only one jumper inside, between pins 8 and 9, nothing more. If the jumper plug is lost, a simple wire jumper inserted between pins 8 and 9 will do the same thing the factory jumper plug does. The jumper plug or jumper wire MUST be inserted in the 9 pin socket, when either the VFO-520 or VFO-820 remote VFOs are not plugged into the 9 pin remote VFO socket. Failure to have a jumper plug or jumper wire between pins 8 and 9 will result in the TS-820's internal VFO not receiving power and the PLL Unit will switch to "Unlock" state causing the digital display to go DARK and complete loss of both transmit and receive functions.

4. I recommend using the 820 schematic(s) when servicing the 820. Relying on memory can easily cause you to go off in the wrong direction.

5. Since you have been handling the 820 quite a bit, I recommend you check the rear panel "SG" switch, ensure it's in the ON position for normal operation. If you are not sure what the SG switch does, I have a video on my website that discusses the TS-520, TS-820, and TS-530 SG switch and what each position, ON and OFF, performs. Click on the video link on my website's main page and scroll down to the SG switch video listings.

6. A used Heathkit, Eico, or other brand of VTVM with the DC voltage setting 1 meg probe will work in servicing the 820. These can be found on eBay are very reasonable prices. Probes can be made if the probes are not included in the sale. Understand that a VTVM or DMM/DVM connected to a circuit in the 820 can affect the circuit's operation. For example, measuring the AGC voltage with a VTVM and 1 meg probe can drag down the AGC buss giving you an inaccurate measurement.

I have high resolution schematics of the TS-820 and the various
boards/"Units" on my website:

www.w5rkl.com

Click on the manual and document link and scroll down to the TS-820 listing.

One additional comment I forgot to mention.

The 820 AF AVR Unit boards are not all the same. They may "Look" the same and "X49-1080-00" board number on the component side may be the same but the foil side has a number that may be different than the board you have. The foil side number appears to be a factory revision which is not mentioned in any manual. Therefore, if you have to replace the AF AVR Unit board for any reason, you must ensure the foil side numbers on any replacement AF AVR Unit board are the same as the AF AVR Unit board in your 820. The AF AVR Unit board's "Xray" view showing the foil side of the board in the TS-820 service manual is the "1381-03" revision of the AF AVR Unit board. Your 820's AF AVR Unit board may have a different foil side number so pay attention to the foil side numbers. I ran into this problem when I service an 820 and wanted a spare AF AVR Unit board. The replacement had a different foil side number than the AVR board in my 820. When I tested the board I found ti didn't work in my 820. The replacement board was fine, it was the revision number on the foil side that made the difference.

Thanks All

Please give me the pin number of the audio board input and how you determined it and then a few steps further:

For example:

1. If you get audio out from applying audio to pin (What Pin) then the audio board is good, go to (whatever is next). If no audio, check board number etc.

By giving me three steps and how you are thinking I'll get a sense for going from schematic to board lay-out to exact location in rig.

I have a signal generator (Wavetek 142 to 10MHz).

Appreciate your help.

Wes and Arnie,

Wes, if that's what Arnie meant by his "5 tubes" statement then I stand corrected.

Arnie, I mean no disrespect but you need to spend some time studying the TS-820's Circuit Description sections in the operator and service manuals plus study the TS-820 block diagram and high resolution schematics (use the links I provided you so you can download, free, the high resolution TS-820 schematics).

The high resolution schematics have voltages at specific points (voltages inside parenthesis are Transmit voltages and voltages not in parenthesis are standby/receive voltages).

You also need to learn what the rear panel RF Volt, SG, and Xverter switches are for and what would happen if the SG and/or Xverter switches are in the wrong position as well as what the RF Volt pot does (you can find this out by studying the TS-820 full schematic and discussion of the controls in the operator's manual).

I am having trouble reaching the Yahoo use Groups with my Macbook Pro and any browser.

I switched to an old Window XP machine which hits it fine. I am also apparently not signing correctly so would appreciate what I am doing wrong from the Group Moderator.

In answer to your other specific questions.

It worked fine before water issue.

Where is the best pin the check (IF BOARD) output and what should it look like. Also IF board pins for DC, so at least I know it is powered correctly.

It was fresh rainwater and noticed in about 8 hours after torrential rain.

I have a Simpson 260, but not a high impedance VTVM. Can the calibrated tecktronix scope due for the VTVM. If not my solid state VMM has at least a 1 Meg impedance.

I received need the probe instructions, thank you. I worked for RCA as an engineer on the rendezvous
radar for Apollo and am appropriately careful around high voltages.

I have all the manuals and had 2 schematics made from Ken's PDF schematic 24" x36".

So what I am looking for is an approach. For example, "If you a lacking audio
start at A because it should be checked first. Then trace DC using Board schematics or whatever".

I am a fast learner once I have a feel for the radio. I can see where all the boards are, controls and in and outputs are clear but more subtle locations I would appreciate help.

I can tell from reading previous postings that the group is outstanding.

I'm thinking the IF board was lowest and exposed to water and have washed and cleaned it but

will check connections again.

The rig looks pretty clean. No visible corrosion.

Thanks for any help you might provide.

That is correct. I am having trouble posting to protocol so any advice would be appreciated. A post was blocked because my signiture was not correct.
Please lets me know how it should look. My Macbook Pro cannot find Yahoo Groups on any browser I've tried.

I know it sound crazy, but it's true. So I have to switch to a windows machine to view it.

I was trying to be modest but perhaps I overdid it. I am an electrical engineer with a great deal of analog experience I am embarrassed to admit.

I would appreciate help from those of you who know the TS820s inside and out to get the hang of checking DC voltages and then signal and injecting signal.

I would start with the IF board but will defer to the groups expertise.
I know what all the controls do and have 24X36 schematics all the bulletins and circuit board blowups.

Just need a little direction as we start so I get a working knowledge of the radio.

Terry, Mike, Wes and all, appreciate your help.

I have tested the radio with all controls in proper position and same as other 820 alongside it which works.

1. Power on
2. Pilot lights on
3. No S meter function
4. No sound.
5. Digital display works, all digits and corresponds to analog frequency.
6. Digital readout changes with band and VFO.
7. T/R switch relay dies not activate on send as with the other TS-820.
8. Relay works in both radios.
9. Could the T/R socket or connections explain the problem?
10. If the socket is the problem, would placing jumpers to simulate a plugged in relay help. It would have to be a problem with the socket
11. Please advise me on whether this is worth pursuing and if so, help with jumpering pins.
12. High Voltage is present as tubes discharge, but HV not seen on S-meter in HV position.

Any suggestions or stratagems welcome. I can meet on the air or provide a telephone number.

Thanks to all,

For clarity please post to this forum.

I can meet on the air or provide a telephone number if anyone is wishes to talk.

I have reviewed the schematic and circuit board breakout and all Service Bulletins from Kenwood. I understand the function of all the chassis switches and controls.

Does the data I provided suggest the T/R switch vs. the IF board or are you led in another direction. Suggestions welcome.

Arnie,

You first say both relays work but then you say they don't work when the SEND switch is activated.

Are you saying if you ground pin 2 on the MIC socket OR you flip the SEND switch UP, the relays do NOT energize?

The SEND switch AND the MIC socket Pin 2 are both wired in "parallel" and both connect through a single wire to the FIX VOX Unit board's FIX3 plug pin 4. They BOTH perform the same function, they ground FIX VOX Unit plug FIX3 pin 4 "SS" terminal. Grounding FIX 3 pin 4 "SS" ground the base of Q9, relay control transistor, resulting in both relays energizing. If grounding pin 2 or flipping SEND switch UP does NOT energize the relays then use a jumper and short FIX VOX Unit plug FIX3 pin 4 (SS) to ground. If doing that energizes the relays then there is an open between the FIX VOX Unit board's FIX3 plug pin 4, "SS" terminal, and the junction of the SEND switch and pin 2 of the MIC socket. All of what I am telling you can be easily seen if you study the high resolution TS-820 schematic I referred you to and the high resolution FIX VOX Unit board schematic link below.

There are "2" relays in the TS-820

1. Control relay on the Relay Unit board found below the chassis in a plug in socket.
2. Antenna change over (RL1), meter control (RL3), Xverter control pin 8 (RL2), and external amplifier relay control (RL4) is found below the chassis next to rear panel and the Final Unit, inside a small metal enclosure.

Both relays are "identical" 4PDT relays. You should spend some time studying the FIX VOX Unit board. You can download the high resolution schematic of the FIX VOX Unit board from my website at the following link

http://w5rkl.com/wp-content/uploads/2014/04/TS-820-FIX-CH-UNIT-HI-Res-SChematic.pdf

From: David Birnbaum
Topic: 49467 Message: 49467

I find I don't have the time to devote to fixing this rig, so I'm offering it here first.

Kenwood TS530S needs work:
Transmitter was working last time it was tested.
Receiver front end (L41) missing; replacement home wound transformer installed. Needs further testing.
Blown regulator transistor in 12V supply. This was due to unfortunate short while testing.

Biggest problem (before blown 12V) was finding a replacement for L41. I've tried a Toko transformer re-wound to make what I thought would be an L41 equivalent. I can supply details of the rewinding.

Case has some rust but otherwise okay.

Can be fixed or used for parts.

I am referring to the control relay. I have a working TS820 and the fixer TS820s. Both control relays work in the good radio. Neither works in the defective radio.

So the control relays are both good but neither work in the problem TS820.

I have all the schematics 24X36 mian schematic all Bulletins from Kenwood and all manuals. I have looked at them all.

Thanks I will try the jumper.

If the IF board was submerged then likely the FIX board was as well. As Mike mentions the relay keying transistor and circuitry is on this board. I would pull and clean it and clean the molex connectors. Also if water was high enough perhaps what you are calling the control relay was submerged. It is not a sealed unit. The relays do not need to be keyed for Rx mode which you report is not functioning but do need good control relay contacts for AGC bus action.

49472. Hybrid Legacy Net Update (July 31, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-08-01 14:26:25 UTC
From: Mark Gilger
Topic: 49472 Message: 49472

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2012. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday net was run by me, WB0IQK. There were 9 stations checking in under good band conditions. We had the following number of radios checking in.

0 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
1 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

The Sunday net was run by me, WB0IQK. There were 20 stations checking in under good band conditions. We had the following number of radios checking in.

4 running TS-520(x)
0 running TS-530(x)
3 running TS-820(x)
1 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:

The VFO-520 will work, plug and play, no conversion necessary, in both a TS-520 AND a TS-820. The same goes for the VFO-820, it will work, plug and play no conversion necessary, in a TS-820 and a TS-520.

The VFOs in both VFO520 and VFO820 are the same analog VFOs in the TS-520 and TS-820.

Don,

Check the rear panel's SG switch to ensure its in the "ON" position. You may have accidentally pushed the SG switch into the OFF position when handling the 520. The SG switch will not prevent you from seeing a peak ALC indication in TUNE mode while adjusting the DRIVE control but it will prevent IP current indication in CW, USB, and LSB mode.

You can see what the SG switch does by going to the following link:

http://w5rkl.com/wp-content/uploads/2014/03/Function-of-the-520-530-and-820-SG-Switch.wmv

Hi everyone, I’m new to this group but not to Kenwoods. I just picked up a TS-530 and everything works great but I am having problems with the modulation. It has a garbled sound. Almost like there is a 60 cycle hum or something when I talk. Almost like it is over modulating with a hum. Never hear a hum when not talking just when I speak into the mic. I have tried 4 different mics and they all sound the same. Hoping someone has run into this before. Thanks Bill WR4G

Bill,
Welcome to the group.

The mic needs to be wired per the attachment. It's also shown on page #6, Figure 2-1 in your operations manual.

Did you wire up the mic plug, or were the connectors already attached to the mics? If you have miswired pin 1 to 4 and 4 to 1 it would produce hum like your indicating.

Mic Plug Breakout:
http://wb4hfn.com/KENWOOD/Docs/Kenwood%20connectors.pdf

Topic: 49478 Message: 49482

Bill,

The MIC 4 pin plug's PTT ground and the MIC audio shield ground cannot
be connected to the same ground.

Front panel microphone socket wiring:
PTT relay connection is on pin 2 and PTT relay ground is on pin 3
MIC audio is on pin 1 and MIC audio shield ground is on pin 4

See the 530 schematic for microphone wiring and microphone schematic
details. If the .01ufd cap lead(s) is/are bad/broken by accident then
it's quite possible your microphone wiring is correct but the fault may
be in the 530's MIC socket wiring, at the socket.

Hi I also think that a poor earthing may cause this due to RF pickup. This would account for the hum only being there when modulating. For some reason RF pickup nearly always produce the standard mains power frequency (50Hz over here) as an unwanted modulation.

Anyone have a reliable source of Type 1 RF capacitors (temp coefficient NPO or COG type) for replacing the fixed padder caps that are switched in across the Pi-network tank and load capacitors.

I found a few values on Mouser and placed order for them today, but they did not have all the values to do a complete recap. I have a TS-830 here now with 3 badly burned caps.

These need to be leaded type capacitors. I have used some with short leads and added lead length to them but would prefer new caps with long leads.

Thanks
Terry K9TW

Topic: 49486 Message: 49486

Hi All,

I have two RF boards for the TS-830S transceivers. These have both been completely gone through including rebuilding the bandswitch. The switches have been taken apart, cleaned, and each contact checked for resistance. After rebuilding, I installed each board in a transceiver and aligned the board. Installing in another radio might require some adjustment. I want $110.00 each for these boards shipped to you via USPS First Class Mail. If your old board is salvageable, we can talk about using it as a trade in. Please contact me at dick@w0nta.com.

Thanks for looking.

Terry,
Wouldn't 500v micas do the job?
If so, I have a wide variety of them here (I have some 1kv micas too)

Jan:

Yes dipped silver mica would work if enough room to get them in. 500vdc is fine for the ones switched in across the Loading cap. The nice thing about the original disc ceramics is they lay flat on each other like a stack of fanned coins.

I found quite a few sites like Just Radios in Canada and other antique radio suppliers that sell silver micas in both 500vdc and 1000vdc.

Right now I am looking at C10 390pf 3kv that is burned black and the top is split open on it. It is one of the fixed padders switched in across the tank capacitor. It isnt an RF cap, but would like to put one there.

Replacing the stack under the loading cap is not much fun!

If I strike out on I may come back to you Jan with the values I need. I really appreciate the offer of help.

Yes I saw it that MCM had them. I buy from them from time to time. However, it is not an RF cap. Mouser has same ones as well. I did buy two of them from Mouser in case I strike out.

I will go back with one of these regular disc ceramics if cant find the RF caps.

At 100 watts output there is approx 545rf volts across the Tank cap and its switched in fixed padders.

If you look at all the padders in the TS-830 you will see KW speced 500 volt RF caps (Type 1) for the ones across the Plate load cap. It sees approx 71 rf volts at 50 ohms and as much as 300 rf volts open circuited. So 500 volt RF caps were speced here. 500 wvdc Type 1 caps were pretty common in the day (NPOs).

My guess is that they did not use RF caps across the Tank cap as hard to find them at higher than 500wvdc. So I am thinking that they went with the 3kv rated disc ceramics across the Tank cap because couldnt find RF caps at 1000wvdc and 500wvdc wasnt high enough.

Not sure why they didnt use 1000wvdc silver micas other than perhaps cost?

Terry,

I have the ceramic disc Type 1, cap that you need, However, you need to replace the C9 and C10 as the 100 will be out of spec or at least highly stressed, this is what I have found on all the ones I have had the privilege of having to rebuild. I know one is 1KV and the other is 3KV, that is all I could get and it was a special order.Email me direct and we can discuss

Extract from the webpage:

TYPES OF RF CAPACITORS

Let us now pass to consider products available on the market. Air-insulated capacitors would be ideal for RF applications, them not being subject to dielectric loss; unfortunately they are very bulky. Making the capacitor with a material having a dielectric constant (k) higher than that of air (k = 1) permits to reduce capacitor size; the formula is very simple: for a given physical capacitor geometry, capacitance is just proportional to k. The market of capacitors for RF applications is today dominated by ceramic capacitors that feature very high k values, up to 10,000 or more.
Selecting a dielectric with a high k yields however some drawbacks, the most important ones being:

the Temperature Coefficient of Capacitance (TCC), which is the maximum change in capacitance over a specified temperature range, increases and tends to show a non-linear behaviour;

the dissipation factor also increases;

tight tolerances are not easy to achieve;

actual capacitance becomes sensitive to the applied vdc (capacitance may drop down to 50% of its nominal value when vdc = Vn);

higher aging rate, a phenomenon due to the relaxation of the microcristalline structure that causes capacitance loss with time, due to a reduction of k. A high-k capacitor could lose up to 25% of its capacitance 4,000 hours after fabrication, but after that capacitance loss becomes much slower.
Type-1 dielectric is material with low k (say less than 200). The TCC for type-1 dielectric, expressed in parts per million per degrees centigrade, is quite moderate. The temperature characteristic of a type-1 dielectric is directly related to its k, as shown in the following table.

Capacitors built with type-1 dielectric are called RF power capacitors; they usually feature a Vn greater than 1kV, an In greater than 1A, a Pm greater than 1kVAr, an almost linear temperature coefficient of less than 1,300ppm/°C and a dissipation factor of less than 0.001. Picture below shows typical RF power capacitors. They are used in applications where temperature stability is important (e.g. resonating circuits) and high Q is required.

Low-capacity (e.g. < 1,000pF) disc-type capacitors with wire leads are most often also built with type-1 ceramics and then have characteristics similar to those of the RF power capacitors.
Type-2 dielectric is material with high k (up to 5,000 or even more). In this case TCC is much higher, varies with temperature, and is usually expressed in percentage of capacity change. A three-symbol designator, e.g., Z5U, X5V, is used to characterize the temperature behaviour of the capacitor (you may have read such strange markings, most often on wire-lead disc-type capacitors). Their significance is shown in the following table.

For instance, the Z5U designator indicates a capacitance variation of +22% / -56% across the temperature range +10°C / +85°C.
Also for type-2 dielectric the temperature characteristic is bound to k, as presented in table below.

The nominal capacity indicated by the manufacturer is referred to a temperature of 25°C. As already mentioned, for type-2 dielectric capacity change vs. temperature is highly variable and non linear.
Capacitors built with type-2 dielectric are usually called high-voltage capacitors, that should not be confused with the RF power capacitors discussed before, though their appearance may sometimes be similar and despite they are both commonly referred to as doorknob-type capacitors, as they appear like small barrels with axial wire leads or screw terminals. The design of high-voltage capacitors is optimized for operation at very high Vn, even up to 250kV. They can also withstand a fairly high irms, while their Pm is usually limited. They typically feature very high and non-linear temperature coefficients (up to 70,000 ppm/°C), a higher dissipation factor (up to 0.015) and a remarkable capacitance variation with DC voltage. Picture below shows typical high-voltage capacitors.

Generally speaking, high-voltage capacitors look taller and sometimes even fatter than RF power capacitors, but it is not always easy to distinguish. A capacitor higher than 5,000 pF having a Vn of 10kV or more is most likely a high-voltage capacitor.
It should be noted that wire-lead disc-type capacitors with a voltage specification higher than some 500V and with capacity higher than 1,000pF are commonly built with type-2 dielectric. Therefore they have characteristics similar to the high-voltage capacitors.
In summary, high-voltage capacitors can also be used in RF circuits, but their usage shall be limited to applications not requiring a high stability of capacitance, and very high pr; conversely they can sustain significant irms values.
That said, let us consider a very well-known product, i.e. the Centralab doorknob ceramic capacitors (now manufactured by ITT-Jennings). They come in several sizes, the most common one being that of models 850 and 858. Model 850 (now renamed HT50), shown below, is an RF power capacitor with capacity varying from 10pF to 500pF, temperature coefficient varying from NPO to N4700, and a Vn of 5kV or 7.5kV. For what concerns In, it seems reasonable to assume that In coincides with the specification they give for maximum current at 30 MHz, which ranges from 7A to 10A depending on capacity. For what concerns the maximum reactive power (Pm), they do not use this term, but they indicate maximum current (Im) at selected frequencies; e.g., for the 100 pF unit, 3.6A @ 1 MHz and 6.8A @ 10 MHz.

Model 858 (now renamed HT58) looks very similar to model 850, the main apparent difference being the fact that the ceramic wall is just a bit thicker, but it has higher capacity, i.e. 1,000pF (a 500pF unit was also available, but now presumably no longer produced). The Vn rating is the same of the 850 model (i.e. either 5kV or 7.5kV), In is 5.6A, and Im is 1.6A @ 1MHz or 3.8A @ 10MHz. Model 858 utilizes type-2 ceramics (type X5V) and should therefore be regarded as a high-voltage capacitor.
It should be noted that other Centralab doorknob capacitors (i.e. the smaller 853-, 854- and 855-types, the larger 857-type and the king-sized 859-type are all RF power capacitors). Therefore model 858, which is probably the most used type, constitutes an exception to the rule

FROM THEORY TO PRACTICE
Let us now consider a typical RF power amplifier (a grid-driven neutralized tetrode) and discuss the type of capacitors that are needed for the functions. Picture below shows a simplified schematic diagram of the amplifier, in which all components irrelevant for the issues to be discussed have purposely been omitted.

Only fixed capacitors are of our interest:

Cpb is the plate bypass capacitor;

Cnf is the fixed neutralization capacitor;

Csb is the screen bypass capacitor;

Cc is the coupling capacitor;

Cpf is the plate fixed padding capacitor (if needed), in parallel to the plate variable capacitor Cpv;

Caf is the antenna fixed padding capacitor (if needed), in parallel to the antenna variable capacitor Cav.
It would obviously be possible to utilize RF power capacitors everywhere, but such a choice could be an overkill in cases where a high voltage capacitor can do the job equally well. As a matter of fact RF power capacitors with the required capacitance and Vn may be unavailable, too expensive or too bulky. In conclusion, it is worthwhile to individually address the various capacitors, with the aim to understand their respective requirements. The plate bypass capacitor Cpb shall be selected with a Vn safely dimensioned with regard to vdc only, as vrms will anyway be very low, the purpose of Cpb being just that of quenching RF on the HV line. This is the reason why Cpb shall feature a low Xc across the whole frequency range, and shall then have quite a high value (at least 1,000 pF, or better more than 10,000 pF for 80- or 160-meter operation). High-voltage capacitors can well be used; on the one hand they offer such high capacitance values in conjunction with the required Vn, on the other hand their limited tolerance and high TCC do not represent an issue for bypassing purposes. With reference to the previously shown graphs, high capacitance will tend to shift the inter-condition boundaries much to the left, but their actual position will depend on the capacitor In, Vn and Pm specifications. For instance, with a 15,000 pF Morgan model-858 capacitor (Vn = 3.5kV, In = 15A, Pm = 1.5kVAr) having an Xc of some -6 ohm at 1.8 MHz, the 15A limit corresponds to an hypothetical pr of about 1.3kVAr, which is lower than Pm. This means that, for said parameters and across the whole ham radio frequency range, Cpb would stay in condition C (ohmic-limited condition). This fact is however not too meaningful as, in practice, irms should be not too high, unless the RFC inductance is undersized. Withn a proper RFC design, much smaller capacitors than the

Morgan model-858 taken above as example can typically be used, even wire-lead disc-type capacitors could do, but verify first that RFC inductance is properly dimensioned at the lowest frequency range, otherwise you may have unpleasant surprises.
The fixed neutralization capacitor Cnf shall have a very high Vn, it being subjected to about the sum of vdc and vprf. To stay on the safe side, select a capacitor with Vn higher than twice the plate voltage. Only RF power capacitors can be used for this application, a low TCC being required for stable operation of the neutralization bridge. The Cnf capacitance is usually very low (just a few pF), a fact causing the shift of the inter-condition boundaries much to the right. For instance, assuming a vdc of 2.3kV and a vrms of 1.7kV, with a 2 pF Morgan model-10 capacitor (Vn = 4kV, In = 2A, Pm = 4kVAr) having an Xc of some -2,600 ohm at 30 MHz, the pr corresponding to the vrms of 1.7kV would be some 1.1KVAr, that is lower than Pm. This means that, with said parameters and across the whole ham radio frequency range, Cpb would stay in condition A (discharge-limited condition). The above mentioned type-10 capacitor would however not be the best possible choice for our case, as its Vn of 4kV offers no margin with respect to vdc + vrms, while its In and Pm would be more than adequate.
The screen bypass capacitor Csb does not require a very high Vn because of the rather low screen DC voltage (usually 300 to 500V, or slightly more); furthemore vrms will also be low because the purpose of Csb is just that of quenching RF on the screen. It should be noted that Csb shall feature a very low Xc across the whole frequency range, much lower than that of Cpb, a very effective grounding effect being needed for the screen. Therefore Csb shall have a very high value (e.g. in the range of several tents on nF for 80- or 160-meter operation). Only high-voltage capacitors can practically offer such high capacitance values; on the other hand tolerance and TCC are not important for bypassing purposes. With such high capacity values, it is very likely that Csb will stay in condition C (ohmic-limited condition) over the whole ham-radio frequency range, though this will also depend on the particular capacitor characteristics. Differently from Cpb, Csb could be subjected to a rather high irms, due to the plate-to-screen capacity which, at 30 MHz, could cause an irms of up to 5A, or even more, to flow through Csb. Among the possible solutions, a widely used approach for Csb is that of using several (e.g. 10 or more) high voltage capacitors in parallel, with a suitable Vn and each sharing a fraction of the total current. This also yields the advantage of a low-inductance path to ground. For instance, using sixteen 1000pF capacitors with Vn = 1kV and In = 0.5A could be adequate even for 160-meter operation, and with such arrangement it could even be possible to use wire-lead disc-type capacitors, though not the small-size types.

The coupling capacitor Cc can be selected with a Vn safely dimensioned with regard to vdc only, it being possible to assume that vrms will not be very high over the whole frequency range. For instance, even an undersized Cc of 500 pF would develop, for a typical 2,500W-class amplifier, a vrms of only 250V or so at 1.8 MHz, a value that is small compared to the plate voltage that could typically be some 3kV. It is not uncommon to see designs in which capacitance is too low for Cc to act as a real RF short circuit over the whole frequency range; on the other hand this is not a problem because, if Cc has a non-negligible Xc, this can be compensated for by a different adjustment of the pi-network elements. It should however be noted that the value of Xc can make a difference in selecting the type of Cc to be used. To make the distinction more clear, let us consider to an extreme case, i.e. that of a high-power amplifier in which the irms flowing through Cc is 7A (such a high value could correspond to either an extremely high power amplifier, or an amplifier with a low plate impedance, e.g. seveal low-voltage tubes in parallel). Two capacitance values are considered for Cc:

Cc = 470pF, to which an Xc of some -190 ohm corresponds at 1.8 MHz. The resulting pr is about 9.2kVA, a value that a high-voltage capacitor would hardly tolerate. An RF power capacitor, such as the Morgan model-832 (Vn = 5kV, Vn = 11A, Pm = 20kVAr) would instead be adequate. It is easy to determine that Cc would stay in condition B (dielectric-limited condition).

Cc = 15,000pF, to which an Xc of some -6 ohm corresponds at 1.8 MHz. The resulting pr is about 290VA, a value that a high-voltage capacitor, such as the Morgan model-858 (Vn = 3.5kV, In = 15A, Pm = 1.5kVAr) can instead tolerate. In this case Cc would stay in condition C (ohmic-limited condition).
In conclusion, suitably sized high-voltage capacitors can be used for Cc, provided that capacitance is high enough. The irms actually flowing through Cc will not be far from the DC plate current.
The plate fixed padding capacitor Cpf shall withstand a high vrms, i.e. the DC plate current times plate impedance. The actual irms will depend on the Cpv value, it increasing for low Cpv values, for a maximum equal to Q multiplied by the DC plate current. Cpf must have a low TCC as any capacity change would result in circuit de-tuning. For even better stability, it would also be appropriate to oversize it, so that temperature will not significantly rise. This means that Cpf shall be an RF power capacitor. Let us again refer to a 2,500W amplifier with Q=12 in which no Cpv is used. From pi-network formulas, it can be easily calculated that Cpf shall have Xc = -120 ohm, and will be subjected to vrms = 1.9kV and irms = 15.8A. The resulting pr is very high (30kVAr), and this is another reason to exclude the use of high-voltage capacitors. A high value of pr is a characteristic common to all capacitors forming part of resonating circuits. An adequate capacitor for a 14-MHz amplifier would be the Morgan model-849, with Cpf = 100pF, In = 18A, Pm = 55kVAr. In this case Cpf would stay in condition C (ohmic-limited condition).
The antenna fixed padding capacitor Caf shall withstand a fairly moderate vrms, i.e. the square root of 50 times the RF power. The actual irms will depend on the Cav value, it increasing for low Cav values, up to a maximum of about the same maximum current as Cpf. Considerations similar to those exposed for Cpf are also valid with regard to Caf, that must also be an RF power capacitor. Referring again to a 2,500W amplifier with Q=12 in which no Cav is used, Caf shall then have Xc = -25 ohm, and will be subjected to vrms = 350V and irms = 14.2A. The resulting pr of about 5kVAr is not as high as in the case of Cpf. An adequate capacitor for a 14-MHz amplifier would be the Morgan model-839, with Caf = 470pF, In = 18A, Pm = 55kVAr. In this case Caf would stay in condition C (ohmic-limited condition).

Terry,
Well, the RF caps have greater current capabilities (at the HV levels).
What if you paralleled two/three regular HV caps? I wonder if one can
get the higher current flow in that way?

Jan

That is certainly an old trick used in taming LC type VFO oscillator drift.

However it was most commonly done by paralleling up small value NPO (Class 1) caps and not regular Class 2 disc ceramics. Pretty common if you needed 30pf to use two 15pf or three 10 pf in parallel. Lower RF current thru each one meant lower temperature rise in the dielectric and less capacitance change so the LC oscillator tank resonance isnt shifting.

So yes the current would split among the paralleled Class 2 caps, but still not sure about the dielectric heating effect. Caps might suffer acute failure or have reduced life span, but might still exhibit considerable capacitance shift.

Biggest problem I see with using Class 2 caps in the Hybrids (even several paralleled) is physical space and shift in capacitance value with dielectric heating from the RF current. This means as they heat up the capacitance value is changing and would be de-tuning the tank. So if they didnt fail but would shift appreciably in capacitance that would be no good.

If I cant find the Class 1 disc ceramics I will probably see if I can fit DM-19 silver micas in the stack space under the Load cap. RF Parts and other vendors have a variety of these in 500wvdc rating.

I really appreciate all the help folks are trying to provide by asking if I have looked at various vendors, but I did quite a bit of Google homework regards the vendors and surplus market. What I was really asking is if any one out there who has replaced the fixed padders and restored rig to factory design would share their source for the factory original Class 1 disc ceramics. I am thinking now that not too many members have experienced loss of a padder? That is of course a good thing.

I personally have had bad experience with using Class 2 disc ceramics as RF padders although have not tried to parallel any. They of course can be used in RF bypass application where change in capacitance value isnt a big deal. Have to think about paralleling them some more.

So I think we have covered this subject pretty well. If I come up empty Jan I will get back to you and see what you have in way of silver mica caps.

Thanks to All

Terry K9TW

Tnx Joe/Terry,

sorry for not replying. I just got back from vacation and have the entire RF board out now and in my paws. Wasnt as difficult as i thought given the destructions you guys provided.

There most definitely is a pin completely loose from the trace of the Driver tube (Pin 2 - Grid 1), a textbook cold/broken solder connection. I should have taken a picture of it.

Fixed that up and washed the bottom of the board with flux remover (it was full of flux) and that made it much easier now to see the quality of all the other connections on the board. Touched up all the Driver tube socket connections and few other suspects. Took a q-tip with some cleaner and then applied some De-Ox-It with another q-tip for all the molex pins.

anything else on this board now that i have it out that i should look at or change while i have it out ?

i am still considering replacing the socket, since there still is some foreign material in some pins that i cant really get out, but i also cant tell if its a problem or not. the broken solder joint was certainly a problem, so i hope that's it.

i wish i hadnt thrown-out/misplaced my wire-wrap tools, thought i'd never use them again - but would be nice for the driver board pin to rf board connection.

By "touched up" do you mean you just re-heated and re-flowed the old solder on there pin to board connection?

I think you would do MUCH better if you used a solder sucker or even solder-wick braid and removed ALL the solder (carefully, so as not to over-heat the board and lift any traces!!) from the bad connections, clean it up well with DeOxit and a touch of a good flux, and then with new solder re-heat and complete the connection.

While you have it already out and in hand, why do it any way that might necessitate that you do it AGAIN??

Old solder and re-flowing hasn't given me the best showing for repairs on older equipment, not since I was a kid fixing junked tube radios for SWL or junk TV's to re-sell. It has always worked best and lasted longer to completely clean the old stuff out and sweat in new. Good conductivity is pretty much guaranteed, then.

How about it, guys? Am I too far off the beam here?

I agree most of the time not easy to get solder to reflow especially on molex pins. They oxidize. I remove all old solder and lightly sand to brite metal and resolder and they wet very nicely then.

I have a Jonard WDUD-2224 wire wrap tool. Can still buy them. Try Web-tronics. I never use it. I cut back to fresh conductor. Clean the post to brite metal and solder the lead wire to the post with just one wrap.

As to other things to look at:

1. Inspect all molex pins under good lite and magnification. I like to plug in the mating connector so it seats the pins in the body and wiggle connector body back and forth side ways and can see the pins floating. I have extra set of plugs and jumpers. If you cant do that then just do best inspection that you can.

2. Good time since you can orient the vertical bandswitch boards better (in horz plane so the cleaner stays in place longer) to apply de-oxit to all the wipers and contacts with artist brush and/or wetted Q-tip. Make sure after exercising the bandswitch that you realign the shaft properly. Just be careful not to press on any of the contacts or bend any. Just need to work the de-oxit into them. You are working in close spacing. I rotate shaft to access the wiper and apply deoxit to it and then rotate both directions to distribute it. You can also spray it in at this time but more wasteful and need to blow out with canned air. I prefer to get it in there and let is soak a little which it will do better with boards in horz plane.

3. Measure Driver tube screen grid divider resistors R36/R37at this time as I find them commonly drifted very high and/or open. Especially R36 100k can be open.

4. Measure Cathode resistor R35 and R41.

5. Clean the rotor shaft wipers of VC-1, VC-2 and VC-3

6. Put a drop of deoxit on the VCO cable plug tip and socket.

I forgot one other bad actor.

If you experience low drive on just 15 and 17 meters it is can be due to bad L36 Driver tube plate choke. Need a LCR bridge to measure it. It is 470uhy and it changes in value over time.

If you can test it now is good time to access it with RF board out. If no way to measure then do a visual. It is small green plastic can and sometimes can see circumferential band of dark brown discoloration about 1/4 way from top down.

From: n612dw@...
Topic: 49432 Message: 49504

hi guys, i put the board back in this morning before i read this, but the choke visually looks clean, no evidence of discoloration etc. as i was looking for any of this sort of stuff on visual inspection when i had it out.

put the board back in, and POOF... I now have copious amounts of ALC and all is again well. RX and TX fixed.

It turned out to be the bogus solder connection on the driver grid pin as the primary problem. Some other molex pins were touched up as well. Now all the driver pins are nice and shiny with proper solder connections. Temperature cycling probably cracked the joint over time.

the whole inside of the radio is very clean, even the final cage shows no evidence of heat related stress. very pleased with the purchase.

I will check it out on some other bands, but it was working fine on all the bands when it went bad on all the bands, so I suspect i am ok with L36 as that problem sounds to be band specific.

Hints and Kinks - i find that using medium sized stainless medical forceps really helps to grab the molex connectors when inserting/removing them without putting any stress on the wires. Their aggressive tooth pattern on their jaws really grab the connector body well. Dont get the ones that are too small, as the jaws are narrow and it puts stress on the body in a small area. Spread it out, get the moderately sized ones. Mandatory part of your bench toolset.

this stuff is really kinda fun to work on and rewarding when fixed.

tnx for the help all. This is an enormously useful resource for those of us (fewer and fewer it seems) who like to keep 'em running and dont mind getting your hands into the box and learn something along the way.

Last week I mentioned in the thread about the new to me TS-520SE that I was having difficulty tuning it up for transmit. In fact, I would get no ALC indication at all. I am happy to report that this is resolved.

I had the chance to go through the alignment procedure in the owners manual and found a number of things were off so I did it a second time and the receiver is working very well. As it turned out, the transmitter could be tuned up when in the CW WIDE position. My coworker, W0MDN, astutely noted this which escaped my notice. Eventually, I was able to net the crystals on the Carrier board and after netting the CW crystal correctly (3.395 MHz on TX, and it settles at 810 Hz below that on RX) everything is working just fine.

Now I just need to make some contacts with it.

The TS-520SE I bought had some in it but they were very loose. I ordered a pair from K4EAA and they fit snug and keep the door from rattling.

Nate:

I dont want to be picky or rain on your parade, but if I understand your post correctly the problem with the Tune loading mode is not "resolved" and everything is not "working just fine" as you state.

All KW hybrids can be loaded in Tune mode and in CW mode. If you cant load in Tune mode the radio is not working per design and for newer people with little experience loading the radio in CW mode means that you are really using a "work around" which requires some heightened sensitivity to short off resonance key down times.

If you still cannot load the radio in Tune mode it is likely that R5/R6 56k ohm screen grid divider resistors on the HV unit board are bad. There is a reason why KW went to the expense of designing and installing the Tune circuit. I suggest you ask your friend to measure the resistors and if open or drifted in value to replace them. Always replace both even if only one checks bad.

Lastly, I am unfamiliar with a CW "wide position" mode?

Hi Terry.

I have the TS-520SE with the narrow CW filter installed. The second switch from the left (immediately to the right of the SEND/REC switch) is the WIDE/NARROW CW filter selection.

Before I netted the CW crystal to 3395 kHz when in TX having the switch in NARROW would not pass the CW signal in either TUN and CW mode. With the switch set to WIDE, the CW carrier was passed in both TUN and CW mode.

I am using TUN mode to tune up the radio into my dummy load. This now works with the filter selection switch in either in the WIDE or NARROW positions, which it should.

I have plenty of ALC indication and everything is solid with good signal reports. Thanks for the hint, if I see issues related to the ALC in the future and the CW oscillator is on frequency, then I will look at those resistors.

The Kenwood DK-5 kit manual is available for downloading at

www.n6wk.com/kenwood/DK-520-Install-Instructions.pdf

It appears, after studying the manual that the circuit might be rather easily reproduced using components/enclosures and wiring found on ebay, Mouser, and possibly your junk box.

The transistor, 2SC460(B) crosses to an NTE-85 which are easy to find. You might find a small metal enclosure that could be used in place of the factory enclosure.

Just a thought.

Hi,
The proc does work when switched in but it reduces the power out to nearly half what is is with no proc.
Can't seem to find anything on this problem anywhere, any ideas?
The radio does drive fine with no proc, I'm stumped to what this problem is.
Dont think it's a allighnment problem.
Thanks,
MW0ZUS

Terry (MW0ZUS),

Have you actually checked the processor alignment by following the processor alignment step 34 page 40 in the TS-830 service manual? That should be the first place to before assuming the problem is not caused by the processor alignment.

I don't mean any disrespect but if you haven't done that then you are guessing the problem is not related to a processor alignment. It's obviously not a speech amplifier problem since the 830 works fine with the processor turned OFF.

The R820 250 Hz cw filter attentuates the signal too much for my liking. The rx cost about the same as the ts 820 in the UK. Why not go for a modern rx? The 820 hasn't FM, 6 metres, weighs a ton, dry joint problems. Not even general coverage. Wouldn't put its value more than $500. I guess I've paid about $400 in my time.

Ian.

49532. Hybrid Legacy Net Update (August 17, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-08-17 18:28:37 UTC
From: Mark Gilger
Topic: 49532 Message: 49532

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.

The Saturday net was run by me, WB0IQK. There
were 14 stations checking in under good band
conditions. We had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-940S with an L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
15 stations checking in under good band
conditions. We had the following number of radios checking in.

4 running TS-520(x)
1 running TS-530(x)
3 running TS-820(x)
0 running TS-830S
0 running TS-511
1 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 80, Sunday☐s total = 85
March 2014, Saturday☐s net total = 82, Sunday☐s total = 73
April 2014, Saturday☐s net total = 64, Sunday☐s total =43
May 2014, Saturday☐s net total = 66, Sunday☐s total = 35
June 2014, Saturday☐s net total = 43, Sunday☐s total = 59
July 2014, Saturday☐s net total = 24, Sunday☐s total = 46
August 2014, Saturday☐s net total = 44, Sunday☐s total = 41 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

A price of $1,000 for an R-820 is way too high. I suspect that price was found on ebay and quite possibly was pushed high from supporters of the seller or the seller using a different eBay user name. Yes I'm well aware that this method of selling/pricing is illegal on eBay but that does not stop those who still do it!

I mean no disrespect but I never believed in the use of the phrase "near mint condition" that is used a lot by hams/people selling old ham/electronic gear.

The R820 has the same PC board and PC board foil run and plug pin problems the other KW hybrids have. The R820 does not cover the entire HF 2 to 30Mhz receive and VHF 6 and 2 meter band as modern day transceivers do. Although it's quite possible to modify the R820 SW bands, 49M/31M/25M and 16M bands, to cover the WARC bands, I would not recommend this to most new hams today since it could easily require significant changes in the SW band circuits. As for what I think a good price for a used R820 is? Again I mean no disrespect but I wouldn't pay more than $385 for an R820 in the condition stated.

Now, having said all that, there are people/hams who have large amounts of disposable income who would spend significantly more than $385 for a used R820 in the condition stated, quite possibly more than $500 but I'm not one of those people even if I had the disposable income to spare.

Good luck if you decide to sell the R820.

Your price may be a little high, it just depends on who wants to add to their collection of old but usable radios. I have one that goes with the TS820,still use it sometimes. I also have a few 520S and 530S and SP. All of these work and are used whenever I find time to get on the air. The one that gets the most use is the 530S.I saw a set of 599 radios that were going for around 999 on ebay. Anyway just my $.02 for what it's worth..

Couple of years ago, it was hard to find one for sale on ebay and if you did, you paid a kings ransom. From what I understand, the R820 receiver is much better than the TS820 and 830. I would consider purchasing a r 820 if I could get it below $400.

???

O...K....

I'M going to guess that you mean your 520S is drifting.

Drifting HOW? Transmit? Receive? Both?

If English is not your first language, no sweat, we'll try to make this work. Try to use more words, and describe your problem in some detail. This is not Morse, the maximum length of the "transmission" isn't critical.

Also, are you at all experienced in working on or with electronics, including high voltages? (By Neptune's Yamsack I never expected to actually have to ASK that of any hams with a license higher than "Novice," but here we are. "That's Progress"??") Do you have the basic tools for this sort of job? VTVM (preferred) or other sort of voltmeter, an oscilloscope, frequency meter, that sort of thing?

Next, have you searched the mailing list web site on yahoo? Look for

520S and drift

in the "Search Messages" (or whatever the exact wording is, I can't recall at the moment, bit it is pretty obvious what the little box means), and you should come up with a LOT of posts about this subject.

Read up, see if any of them sound like your problem and perhaps try to do what they did to correct it. Get back to us if you figure it out, maybe someone else will be helped down the road. (It's the raison d'etre for this list's existence, after all.)

Also, if you have NOT gotten the documents available for the radio (User's Manual, Service Manual, schematics, etc.) off of the club members' web sites, those are all free for the downloading, and you need to get them to help fix (and just use) the rig. Study the schematics and use the 'Circuit Description' section of the service and user's manuals to get a feel for which does what inside the radio. It's good to know what is going on, to be able to get the most out of your radio.

Try your post again, look into the resources I mentioned on the yahoo and various list members' sites, and then we'll see what we can do.

Regards,

I dont know about your basic electronics background or ability to read schematic?
If you can look at schematic of audio board you should see that the VOX Delay is controlled by Q13 discharging capacitor C49 which is a 3.3uf cap.

It is a simple RC circuit with the resistance element coming from VR5 250K ohm delay pot and fixed resistor R69 47k ohm. With VR-5 set for max resistance you then have total of 297k ohms. RC time constant is then approx .984sec or 984 millisec which is close enough to call it 1 second of delay. With VR5 set for minimum resistance then RC time constant is 3.3uf x 47k ohm or approx .155sec or 155 millisec of delay.

One way to get longer time constant would be to change out C49 from 3.3uf to:

4.7uf = 1.4 seconds
5.6 uf = 1.66 seconds
6.8uf = 2.0 seconds (that I would think would be sufficient long time?)

Tantulums typically used for timing application, but electrolytic could be used. I just used standard value electrolytics for the above calcs.

I forgot to mention if you have a first generation TS830 your audio board may be a little different regards VOX Delay. If you have a C48 and C49 in series then come back and we can discuss some more. Early audio board had two delay time constants one for CW and one for SSB modes. This was controlled by an additional transistor switch Q14. If you dont have a Q14 and C48 then changing value of C49 will work as I have noted.

Carlos
To close this thread out I will describe the changes you need to make to your early generation TS830 AF board.

1. Fold AF board over to access foil side.
2. Remove C48 and C49. Leave Q14 in place as it will be isolated and no longer function.
3. Install a 6.8uf electrolytic or tantalum in the old C48 location. Connect the positive lead to the junction of D11 cathode and Q13 collector. Connect the negative lead to the pc pad where the negative lead of original C49 was located.
4. Becareful soldering over the radio so you dont drop any solder flash into the radio. Becareful clipping the leads off the newly installed 6.8uf cap so they dont fly away into the radio and not be recovered.
5. Fold the board back over in place and install the retaining screws.

You should have a VOX delay now with max of approx 2 seconds and the dual time constant feature has been defeated.

I believe that this change was first published in one of the early International Radio Kenwood Users Group Newsletters. I had it in my TS-830 notes, but dont know for certain the source document. I should also mention I have not implemented this change and have no experience with it. What I do know is Kenwood did eliminate Q14 and C48 in the 2 million series radios. All the AF boards that I have seen have the board traces and pads for it, but the function was eliminated.

James,As other posters have mentioned, we don't know just how experienced you may be with "older" rigs. The first thing I thought about was... "How long do you have the rig powered on, when you see this drifiting?" If you throw the power switch and start sending right away, you may wish to add "go get some coffee or tea" after you apply power. Tube rigs do take a little time to stabilize from a "cold start".

Hope you don't have serious problems..sometimes, simple things work wonders.

Good luck, and please keep us posted.

I recently obtained a TS-520. It appears to work fine on 20 m and 40 m, the only two bands (antennas) I have tried.When trying a to tune into a dummy load on 29.1 I noticed no noise in receive. I tried the 25 kHz marker which works fine on all other bands, nothing on 29.1.

I'm hoping it's a tuning issue. I have a 50 MHz o-scope and hope to get to this after a short trip.

Any thoughts or advice?

Gary,

I can't say for sure but it's possible your problem may be caused by an 11 meter modification. The TS-520 is and has been a prime candidate for "shade tree technician 11 meter modifications" applied to a TS-520.

You can look on the HET OSC crystal board, the crystals are mounted on the rotary switch (see the TS-520/520S/520SE service manual for details on finding the HET OSC crystal board), to determine if any of the 10 meter crystals have been changed so the 520 will operate on the 11 meter band or the frequency range from above 27.405Mhz (channel 40) to the bottom of the 10 meter band, 28.0Mhz.

There are 3 factory installed 10 meter crystals to cover 28.0, 28.5, and 29.7Mhz bands. The crystal frequencies for each of these bands are as follows:

28.0 - 36.895Mhz
28.5 - 37.395Mhz
29.1 - 37.995Mhz

If your 520 has been modified to operate on the 11 meter band or the frequency range from 27.405Mhz to 28.0Mhz, a different crystal will be required. For example, if your 520 has been modified to operate on channel 1 and above, a different HET OSC crystal for one of the 3 10 meter bands will be required.

If you are going to do any servicing of your TS-520 you will need the service manual for the model of 520 you have, there are "3" different models of 520s. You will also need to have and be able to properly use test equipment, and have experience troubleshooting using test equipment. You did not state what level of electronic knowledge, troubleshooting and repair experience you have, only that you own a 50Mhz scope.

If you dig around in the list archives you will find a posting from me with step-by-step instructions on how to unscrew the inscrutable and get your 520 back to being a ham rig instead of an un-type-accepted unlawful chicken-band. (This is not an FCC-approved rig for 11 meters. The mod is not type-accepted by the Feds.)

I think I included the contact information for getting the correct crystals. It's a very simple mod, and then you just run through the alignment procedure in the manual. Bob's your Uncle, Fanny's yer Aunt shortly thereafter.

I would take the time to look at all of the slugs in the tuning coils while I was in there, too. Make sure none of them are cracked or anything. There are a lot of posts in the list archive on yahoo about getting a stuck slug loose, using silicone lubes or DeOxit or a hot pencil soldering iron, loads of things. Look into that if any of the slugs are stuck. Be sure to use a non-metallic (plastic or composite) tuning slug tool. Metal ones affect the tuning, and it changes as soon as you pull the tool away from the coil. Wood, plastic, composite, whatever non-conductive, non-reactive material you can find. There are sets of these tools available for a few dollars from various electronics tool suppliers. You need some.

DO take the alignment instructions exactly as they are given in the manual. It makes a difference which one goes first, as they affect each other. Tuning one will change another one, so you do them in the order given to take that into account.

DON'T try to brute-force the tuning slugs into turning while doing the alignment. Not only do you risk cracking the ferrite tuning slug, but you can deform and even destroy the coil itself, and then you're into a mess getting a new one on there.

(Replacing the whole board becomes an option at that point, one highly-thought-of by people who have worked on these radios for a long time. Heeding their advice is recommended....)

49558. Kenwood Hybrid Net Update (August 24, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-08-24 18:52:31 UTC
From: Mark Gilger
Topic: 49558 Message: 49558

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2012. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday net was run by me, WB0IQK. There were 14 stations checking in under good band conditions. We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
5 running TS-820(x)
5 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-940S with an L4B amplifier.

The Sunday net was run by me, WB0IQK. There were 12 stations checking in under good band conditions. We had the following number of radios checking in.

4 running TS-520(x)
1 running TS-530(x)
3 running TS-820(x)
3 running TS-830S
0 running TS-511
1 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 82, Sunday□s total = 73
April 2014, Saturday□s net total = 64, Sunday□s total =43
May 2014, Saturday□s net total = 66, Sunday□s total = 35
June 2014, Saturday□s net total = 43, Sunday□s total = 59
July 2014, Saturday□s net total = 24, Sunday□s total = 46
August 2014, Saturday□s net total = 62, Sunday□s total = 53 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Greg,
Good luck. those are hard to find. What I did was
just get some DB-25 connector pins and put those
on the end of the wire that I used and stuck them
into the appropriate hole on each plug. It's been
that way for several years now.

Greg, is there a connector at each end ? One being a 9 pin plug looks like it will fit a b9a tube socket
The other end fits the ts 820 a more bulky version of rs 232 type, but isn't a rs 232.

49564. repair of VFO-230

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-08-25 04:42:51 UTC
From: ve3pie@...
Topic: 49564 Message: 49564

My VFO-230 is doing strange things. It sometimes freezes, or may indicate an incorrect frequency, or may be missing some of the sides of the 7 segment display producing incomplete numbers, and sometimes other strange things. The only way to fix it is to turn off the TS-830S, unplug the AC power of the VFO for 5 minutes (not just a few seconds), then replug AC power to the VFO, and then finally turn on the rig.
I have no technical knowledge to fix this. Who can I send this to for repair?
thanks, Fred VE3PIE

One thing to remember is that the VFO-230 always has to have AC power. If you have a master AC switch that shuts off all your AC when you're not operating, the next time you turn everything on, the VFO will indicate random numbers, partial number segments, incorrect frequencies, or other weird stuff and be generally useless. The general reset for this is, turn the 830 off, disconnect the VFO cable, wait a minute, plug the cable back in, and turn the 830 back on. This happens to me all the time because, when I'm not at the operating position, all the AC to everything is shut off.

The R-820 IS much better than either the TS 820S or the 830.... More controls to fine tune, a 10db per selection attenuator from 10-40db, better noise figure, the triple conversion is super especially when using the notch which is @50khz...

Sweet,

I'm going to pair mine with my TS 820S and probably will never use the 820 receiver again...

Greg

49572. Selling Kenwood hybrids...

Yahoo group: TS-520_820_530_830 (2014)

From: ke5ftf@...
Topic: 49572 Message: 49572

I have decided to sell all of my Kenwood hybrids parts this fall...I have 30 radios in chasis with some parts removed...
I have part bins for the 520, 520S, 530S, 820, 820S & the 830S...

I plan on taking an inventory in September after it cools down a bit...

Please don't ask me for a price at this time, it will take time to inventory...
I will provide sharp pictures with the inventory...

We are downsizing to a motor home so our space is limited...

I will offer to this hybrid group first & then to QTH.com on their Classifieds...

We are located in Wichita Falls, TX (120 miles NW of Dallas)

I was thinking that a group may get together for the purchase once I price it all out...
Must be picked up in Wichita Falls, TX, no mailing or shipping...

Many Thanks,
Bob

Fred,

The issue your finding is most likely the caps have dried or have leaked. I have 3x VFO230, and only one has displayed this problem, which was fixed with cap replacement, crappy job to do but at least it fixes the issue.

Subject: Re: [TS-520_820_530_830] repair of VFO-230

I had a similar problem with a VFO-230.

The bad news was that the microprocessor was failing.

The worst news is that I was not able to find a replacement.

Subject: [TS-520_820_530_830] repair of VFO-230

My VFO-230 is doing strange things. It sometimes freezes, or may indicate an incorrect frequency, or may be missing some of the sides of the 7 segment display producing incomplete numbers, and sometimes other strange things. The only way to fix it is to turn off the TS-830S, unplug the AC power of the VFO for 5 minutes (not just a few seconds), then replug AC power to the VFO, and then finally turn on the rig.

I have no technical knowledge to fix this. Who can I send this to for repair?

thanks, Fred VE3PIE

My VFO-230 hasn't exhibited any of those symptoms.yet. Should it start acting up, is there some way to differentiate the symptoms such that one could conclude the problem is curable by replacing caps that "have dried or have leaked"?. Versus the scenario of replacing caps only to find the problem is the microprocessor?

Hi Ian,

Yes, that is the cable. It has a 9 pin connector on one end to plug into the TS 820S remote VFO plug. The other connector (hard to find one) is a 16 pin rectangular connector that plugs into the back panel of the R-820

I can only speak for my experience.

Shortly after buying the VFO-230 locally here, it started acting up, not tuning correctly, digits displaying incorrectly. I probed the digital signals on the microprocessor and found one of the signals that communicated with the peripheral extenders was out of spec.
I eventually cut the pin to make sure that it was not being loaded down with any external circuitry – no help. As I was testing the output levels continued to degrade.

I would suggest that putting a scope on the power supply voltages at the chips should tell you if there is a power supply problem. You shouldn’t see any ripple. A quick test for caps is usually to just bridge another cap over the existing ones. If the problem goes away, the caps should be replaced.

Chris W7JPG"

On the bottom of the VFO-230 service manual schematic, there is a set of scope traces that can help in isolating problems in the VFO. The schematic is part of the TS-830S/M service manual. The 3rd edition is the most up to date.

Ok Greg I have 1 or 2, But I can't find them. I'll keep on looking. Always thought the 9 pin plug was too good to scavenge. Pre e.bay days here in the UK, we had to depend on a newspaper named LOOT. The R820 sold for less than a 1/4 of its original cost. Not many advertised at that price. 73 Ian g3yrq.

I have done the cap replacement on about 20 VFO230s and it has fixed the problem everytime. The VFO230 has had a couple of circuit upgrades, just like the 830 and 530 etc. I leave my VFOs connected and power applied to them all the time, never had an issue.

Hello All,

I've decided to sell my TS-820. It has been gone through by a professional tech that specializes in Kenwood hybrids and is in 100% excellent working order. Fresh finals and driver, 100W + output on all bands. Receiver has been aligned and performs flawlessly. While it was on his bench, the technician also made an awesome digital display unit for the rig as well. The read out are red LED's and it looks and WORKS perfectly. This radio has no issues and is ready to provide many years of reliable service. This is no project rig by any stretch. It's ready to go. I'm looking to finance some other items, so its time for a new home. I have an ad on QTH classifieds that has a picture of the front of the radio with display. I can provide many other hi-res photos for those interested. I'm asking $400 shipped to the lower 48. AK and HI will be actual shipping costs. Please contact me joeloverti@... or 414-418-9335 for more info or for other pics of the radio.

Thanks,

Joe

Hi Daniel,

I'd be glad to provide you the additional photos of the rig. Can you give me a personal email address? I'm not sure if it would be proper for me to send them via the forum's address. The digital display for my TS-820 was created for me by a gentleman that professionally services Kenwood hybrids in NC. The radio belonged to my uncle who is now SK. He never was able to pass his general exam and therefore never used the radio for more than SWL-ing and listening around the bands. By the time he passed away, and the radio became mine, the rig was in need of some tuning up that I lacked the technical expertise to do myself. I sent the radio off to "Old Ham Dave" (google him) last year and he completely restored the radio to Kenwood specs. I also asked him about building me a display for it. He built one for my radio and it works terrific. I've been very pleased with it.

Please give me your personal email and I'll send pics your way. Please indicate if there are specific areas that you'd like to see in particular.

Thanks,

Joe

Fred,

Sorry for delay. I only change the electrolytics, have to be careful with not over heating foils so you don't lift them and create other porblems. The power supply electros are the biggest problem. It is the same for most of this era of equipment, as example, the SM220 HV PIO caps are now starting to fail due to age, getting NOS is not always the best option, but thus far I have been very lucky to have some from the late 90's manufacture era which has solved the problems

I have a TS-520SE with matching external speaker and VFO. The antenna connection of the TS-520SE is connected to the input of the MFJ-949C Antenna Tuner via a 3ft RG-8x Coaxial cable. The output of the Antenna Tuner is connected to 50ft of RG-8x which then connects to an inline lighting arrester that is outside of the house. The end of the RG-8x that is connected to the lightning arrester is looped 10 times to form a Balun as recommend by MFJ. The other side of the lightning arrester is connected to a MFJ-1778 G5RV antenna suspended between a tree and the second story of my house. The antenna is suspended with non-conductive nylon rope. Also, the lightning arrester is grounded using a 4ft solid 16 gauge copper wire connected to a copper coated grounding rod pounded in the ground.

My question is what would you recommend for station grounding. Some articles like the one I found on EHAM (http://www.eham.net/articles/21383) recommend no grounding at all.

Is the grounding screw at the back of the TS-520SE there for purely AC ground? As you are aware the TS-520SE does not have a grounded plug.

Does the TS-520SE require a good RF ground as well?

Thanks,

John

> My question is what would you recommend for station grounding.

You won't go too far wrong if you follow the ARRL grounding guide:

http://www.arrl.org/grounding

All kinds of good information there.

Neatness, by the way, does NOT count for grounding. Shallow, sweeping curves, NOT tight, precise, 90-degree bends in your ground wires. Also, NO METAL SUPPORTS THAT ENCIRCLE THE GROUND LEADS. Any sort of metal (conductor) which completely encircles a ground lead, and this includes things like eye-bolts and metal stand-offs, is also called

A CHOKE.

Lightning surges may very well not (OK, just plain -WON'T-) pass down the ground wire at that encircled spot, and the surge WILL find somewhere else to which to jump at that point. Pray to your favourite deity IT AIN'T YOU.

Another thing, make certain that ALL your grounds are tied together and are at the EXACT same potential as the house power system ground. If you install a second ground system and do NOT tie it to the power ground, it WILL be at a different potential in comparison to the power lines, and WILL cause a "ground loop." If you have never had an RF burn from touching a cabinet knob or a drawer handle or something in your shack because there was stray RF running loose, well, I don't recommend it as something to seek out and put on your "bucket list," that's for sure.

(The 'stray' RF will be running down that ground loop, sure as you're born. And it will HURT you when it jumps to your fingers, out your hind end - if you're lucky- or your gonads - if you're not - to the frame of your chair, and out through the floor or something close by.

(I wish I was kidding and NOT speaking from experience - metal surplus military desk chair in the shack. Got me down the arm, out through the blue jeans -via the ol' danglies... ZOT!! I woke up, on the floor, with a VERY unpleasant burn in a VERY unusual place, and it was rather hard to explain to the doctor.) The burn if will leave where it enters AND where it leaves will be a thing you remember for a LONG time.)

Here's a link to Tom, W8JI, grounding webpage.

My shack which is a 10 x 20 outbuilding in the back yard, is grounded according to Tom's diagrams shown in the link below. This put the shack, house and antenna switch box system at the same ground potential. About 2 years ago lightning struck an 80 foot tall pine tree next to the shack (about 15 feet away), no damage, pulse or otherwise, occurred to any gear in the shack or the house.

Our city does inspections of electrical equipment with in the homes. They exclude coffee post, toasters, blenders and some TV's. I had to replace the cords on my 530 and my 830 to be up to code. They require all equipment to have the 3rd wire ground. Not only did I have to change the cords, I had to rewire several sockets for the 3rd wire ground. They also require the all transmitting equipment have a station ground separate from electrical ground. Now, lets see, by changing the cord to a 3rd wire ground and then a separate ground from the post on the radio, means that you are tying the 2 grounds together. I questioned that and they had no answer and said they would get back to me. That was 2 years ago and nothing heard. I guess they can't figure that one out. DAHHHH!

Fred,

Sorry for delay. I only change the electrolytics, have to be careful with not over heating foils so you don't lift them and create other porblems. The power supply electros are the biggest problem. It is the same for most of this era of equipment, as example, the SM220 HV PIO caps are now starting to fail due to age, getting NOS is not always the best option, but thus far I have been very lucky to have some from the late 90's manufacture era which has solved the problems

Station Grounding
Thu Aug 28, 2014 7:22 pm (PDT) . Posted by:
jbdkz@...
I have a TS-520SE with matching external speaker and VFO. The antenna connection of the TS-520SE is connected to the input of the MFJ-949C Antenna Tuner via a 3ft RG-8x Coaxial cable. The output of the Antenna Tuner is connected to 50ft of RG-8x which then connects to an inline lighting arrester that is outside of the house. The end of the RG-8x that is connected to the lightning arrester is looped 10 times to form a Balun as recommend by MFJ. The other side of the lightning arrester is connected to a MFJ-1778 G5RV antenna suspended between a tree and the second story of my house. The antenna is suspended with non-conductive nylon rope. Also, the lightning arrester is grounded using a 4ft solid 16 gauge copper wire connected to a copper coated grounding rod pounded in the ground.

My question is what would you recommend for station grounding. Some articles like the one I found on EHAM (http://www.eham.net/articles/21383) recommend no grounding at all.

Is the grounding screw at the back of the TS-520SE there for purely AC ground? As you are aware the TS-520SE does not have a grounded plug.

Does the TS-520SE require a good RF ground as well?

Thanks,

John

Yes indeed. A sterling example of when stupid bureaucracy meets physics. Physics will win out, every time.

Problem is, that small ground pin connection isn't up to a lot of current, balancing your two ground systems ("separate" one and the original power system ground). You really ought to use something a lot beefier and tie them together for real, instead of relying on a little 14-gauge and the house ground wire through the panel.

The way it is will keep the ground loop issues at bay (usually, there might be some odd situations where you get some RF on cases if the 3rd-pin isn't making a solid connection - corrosion for instance on the chassis of a transmitter or amp). But if you take a lightning bolt it I can't see the power cords holding all the surge current and bleeding it off quickly enough to ground.

I work on a very short budget for this hobby. Scavenge and scrounge is the order of the day, every day. The one thing upon which I spent the most of my limited funds was the grounding system. Copper-clad rods and heavy-gauge wire (and even some woven-wire straps on a UPS system for the server rack - only marginally ham-related but in need of a good ground), is rather nastily expensive. Of course now I hear that copper prices have dropped a bit, wouldn't you just know it? (Bet it still ain't cheap!)

KENWOOD TS-520_820_530_830They also require the all transmitting equipment have a station ground separate from electrical ground.

As I’m sure you know, the NEC requires all grounds to be tied together. The city inspector is wrong.

The pages written by W8JI, http://www.w8ji.com/station_ground.htm, are entirely correct.

That sounds typical from an "electrician" stand point. Electricians do not deal with RF etc, they deal entirely with normal house AC voltages/wiring/grounds.

You can do what you want but if it were me, I would make darn sure my shack ground is at the same ground potential as the house ground by connecting them both together with large solid copper wire!! You can see how this is done on W8JI's website link I provided!

Topic: 49598 Message: 49602

Maybe although I go with "they didnt know what they were talking about"

At our "farm" we have 40 KW of solar energy (rooftops, dedicated panels etc), 3 200 amp electrical services and the WB5MZO station tower(s) and they are all tied together ground wise
everyplace I can tie them together with very large wire...and the electrical folks were very
very happy about this.

you are asking for trouble if you start running "separate" grounds. back in the day (going through
college and undergraduate) I helped put in satellite earth stations for commercial TV installations
(including WTBS when they were at Techwood) and we grounded "everything" together.

Robert WB5MZO and soon TA1 something...

>> Our city does inspections of electrical equipment with in the homes. They exclude coffee post, toasters, blenders and some TV's. I had to replace the cords on my 530 and my 830 to be up to code. They require all equipment to have the 3rd wire ground. Not only did I have to change the cords, I had to rewire several sockets for the 3rd wire ground. They also require the all transmitting equipment have a station ground separate from electrical ground. Now, lets see, by changing the cord to a 3rd wire ground and then a separate ground from the post on the radio, means that you are tying the 2 grounds together. I questioned that and they had no answer and said they would get back to me. That was 2 years ago and nothing heard. I guess they can't figure that one out. DAHHHH!

>> Sorry for delay. I only change the electrolytics, have to be careful with not over heating foils so you don't lift them and create other porblems. The power supply electros are the biggest problem. It is the same for most of this era of equipment, as example, the SM220 HV PIO caps are now starting to fail due to age, getting NOS is not always the best option, but thus far I have been very lucky to have some from the late 90's manufacture era which has solved the problems

49603. Re: [TS-520_820_530_830] Station Grounding

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-08-29 17:26:00 UTC
From: jbdkz@...
Topic: 49595 Message: 49603

So based on this statement in the ARRL Grounding page (http://www.arrl.org/grounding)

If you use a "complete" antenna like a dipole or a ground plane (that is, one that doesn't require your feedline to connect to ground), you don't need a RF ground, as long as you keep common-mode currents off your feedline. A "current" or "choke" balun is most commonly used for this.

My G5RV is a type of dipole antenna and I do have the recommended balun. Is it safe to assume that I only have to worry about Safety Ground and not RF grounding in the shack?

Thanks,

John

Hi Bill,

That's interesting. Is it a service that is offered to residents or do they enter every single dwelling as part of some city ordinance?

I currently have 8 antennas up, only one is not fed with grounded shield coax. It's twinlead goes directly to a tuner connected to the radio's ground thru a few feet of 1/4 inch flex hardline coax and a coax switch. Never had a lightning problem in 53 years.

My radio is Ham Radio...CW is Real Radio

IMO, it's not really that huge of a job with the correct tools and patience. I had fun doing mine. I'm almost sad that I'm about 9 caps away from completion. Maybe I'll make a business of it depending on if I can get the poor thing working again.

Nothing like a sense of achievement knowing that you have repaired it. No reason it shouldnt work as long as you have returned the caps back the way they came out of board and that you used a static strap. The early VFO230's had some caps in opposite to the way it was orientated on the board, bad screen printing setup. Let us know how you go when you finish

Hello All,

Well, I've been thinking about this issue for a while, but wasn't going to raise it here since it isn't specifically Kenwood related. But since this thread is already well along, I'll chime in.

I have a Kenwood TS-830S that I haven't used yet. No station at the house at present. I have read a lot about grounding and understand about putting all the grounds together, AC and RF. From what I read, however, it would be best to run my AC ground to the main ground at the breaker box. The shack location would be a good 50 to 60 feet from there and my understanding was that it would be best to run the ground on 6ga to 8 ga wire buried in the ground, running around the house to the breaker box, then tie the RF ground to two or three ground rods connected by a copper strip and connected to this wire running to the breaker box ground.

When you figure the cost of the heavy wire, the copper strip, at least two ground rods and a ditch witch to keep it in the ground, we're talking about several hundred dollars I don't have.

I do have lots of copper and iron pipe running into the ground in the house to hook to, but wasn't sure this would be OK. I thought about grounding the radio to the three prong outlets and just using an "field day" type antenna that I could put up and take down, maybe a vertical dipole which wouldn't require a permanent ground beyond tying into the house ground through the local outlet plug. I'd think this would protect me from RF in the shack, but, of course, not from lightning, which would be the reason I would take the antenna down when not transmitting.

Any advice/discussion greatly appreciated.

Roy, KI4HAG

> least two ground rods and a ditch witch to keep it in the ground,

"Ditch Witch"?? It is to laugh! Such jocularity, so much entertainment....

Son, lemme innerduce ya to this hyar thang what I used. It's called

a SHOVEL.

Us farmer types don't call a spade a spade, we generally just say shovel
unless it happens to BE something like a tile spade. ("Know your tools.")

I -wish- I had the cash to hire a powered post-hole auger (there's some
fencing needs to get put up out there), or a ditch-witch (drainage tile
for the front of the house), or a lot of other things.

With my arthritis, it would be simply glorious.

With my "budget," it would be simply impossible.

For the ground I put in, it took me the better part of a week, digging a
bit when I could, to lay the ground strap around roughly 70 feet of the
perimeter of my house.

I expect to be occupied for at least three more weeks with ripping off
the tongue and groove flooring on my front porch, four feet at a time,
and replacing it with sheet goods instead. (Have you priced 3/4 inch
tongue and groove lately?? I have, and that's why I'm putting down OSB
where the 125-year-old tongue-and-groove planks used to be....)

You just have to dial back the old expectation-meter to something
reasonable for 'part-time,' and 'by hand,' and the whole thing
eventually gets done.

Just not in one day.

"This is my hobby; I do it for fun."

Repeat that mantra every time you get into some onerous chore connected
with your leisure-time pursuits.

If that was a civic requirement I would be petitioning the city for removal of the law or for changing it to match well-known "best practice." (NOT suing them for money/profit.) They need to consult someone who has a clue before making such statements or laws.

It can be easily proven that a secondary ground which is not bonded together with the primary house mains ground CAUSES rather than ameliorates hazards. Having different potentials WILL create a current flow, it's just physics and some fool lawyer with a pen cannot make it otherwise. (Just like Pi cannot be made to equal 3.0 exactly, another piece of foolishness once considered by morons with legal and not mathematical degrees, and a 'mandate from the people.' The 'people,' bless their black and flabby hearts, know nothing about electricity.)

(In 1897 the Indiana House of Representatives unanimously passed a measure redefining the area of a circle and the value of pi. (House Bill no. 246, introduced by Rep. Taylor I. Record.) The bill died in the state Senate. It was never actually passed as a law, anywhere, despite the internet meme to the contrary in re a mythical Alabama legislature which supposedly passed this bit of foolishness into law in that state. Not even in Alabama.)

The U.S. and Canadian national electrical codes BOTH back this up. Don't know about many European ones, not the E.U. code in particular, but both the (West) German electrical code in the 1980's, and the U.K. electrical code at that same time, covered ground bonding and ground loops. I was stationed in W. Berlin and had to prove to the (German) electrician on base at Tempelhof that the receive-only equipment in my barracks room (NCOs got a room to themselves, thankfully) met code for grounding, among other things. They disliked the long-wire vertical antenna dangling out the window, 20-plus meters up, mostly. I did and it was, so I got to keep my old (tube-based) Heathkit.

Getting this idiocy removed as a civic requirement should be a walk in the park, in any jurisdiction. Please, bond your grounds together, for your own, and your family's and friends', safety. Going SK happens to all of us but there's no reason to rush things.

49614. Hybrid Net Update (August 31, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-08-31 22:19:41 UTC
From: Mark Gilger
Topic: 49614 Message: 49614

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st, 2012. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday net was run by Jimmy, WB2KNR. There were 8 stations checking in under poor band conditions. We had the following number of radios checking in.

1 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

Jimmy was running his TS-520.

The Sunday net was run by me, WB0IQK. There were 9 stations checking in under good band conditions. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday□s net total = 94, Sunday□s total = 85
December 2013, Saturday□s net total = 87, Sunday□s total = 103
January 2014, Saturday□s net total = 71, Sunday□s total = 82
February 2014, Saturday□s net total = 80, Sunday□s total = 85
March 2014, Saturday□s net total = 82, Sunday□s total = 73
April 2014, Saturday□s net total = 64, Sunday□s total =43
May 2014, Saturday□s net total = 66, Sunday□s total = 35
June 2014, Saturday□s net total = 43, Sunday□s total = 59
July 2014, Saturday□s net total = 24, Sunday□s total = 46
August 2014, Saturday□s net total = 47, Sunday□s total = 50 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Anyone have a non-functioning TS530 and TS830?

I am looking for radios that I can use to harvest parts to keep other KW hybrid owners radios on the air. Prefer that all the boards be in place and not significantly cannibalized. Cosmetic condition is not important. Dont have to have covers. They can be beat.

In addition to paying for the radios I will also pay for UPS or Fed Ex to pack for you if that helps.

Please contact me off the List.

Thanks
Terry K9TW

49616. Selling ALL of my hybrid Parts...

I have decided to sell all my Kenwood Hybrid parts...
Kenwood TS-520 to the 830S...
Must come to Wichita Falls, TX to pick up...
I have taken an inventory with my normal selling price for each part that I have...
I built an Excel spreadsheet so you can see what I have...
I have also taken pictures so you can take a look...

I would prefer to sell all to one buyer or even a group of buyers that could take what they want...

I will not sell a part out of the inventory at this time...

Parts so far total over $30,000 but realize it would take many years to sell all of the parts, so just a fair offer...

I could split up the sale on the different models if needed if I can’t sell all at once...

Be willing to take an Icom Pro-3 station or a Ten-Tec Orion II station on trade...

Send me an Email off board & provide your Email & will email you the Excel spreadsheet & pictures...

Thanks,
Bob

Actually it looks almost new! Tickled to get one. Was saving pennies back in the 80's when they went away.

Did some touch up alignment today. S Meter is on the money, RIT, etc., after considerable warm up. Is there something to look for in common warm up drift problems? It's probably within the KW specs, but nothing like the ARRL test result.

I notice pics in the files of what I assume are DDS VFO's. I'd like more info on that. Externally, of course. What sort of output levels do the remote VFO's such as the 230 output? I have an N3ZI in use with boatanchors that would probably work with some switching. Any info appreciated.

BTW it's Gold Label with the KB-1! Don't hate me just cuz i'm beautiful

Some dealer pulled the filters, of course. Also the matching speaker turned out to be from a 940. I have more collecting to do.

Darrel, N0DBX

Doing more research on the radio and I have found all the controversy about the "Gold Edition". Correspondence with the set indicates it was purchased used from Floyd Electronics in 1985 and there was no mention of label color or such in the letters.

-------Remember writing to someone to get a radio price?!?

The serial begins with the number 2 and it never appeared to have extra filters, has the K5 Murata, etc.

So, hope I didn't open a can of worms. I said I was new! The rig is exceptionally clean, though. Still on the bench. Tightened screws, adjusted the RIT and Notch. Listened to myself on the Icom. Sounds good.

Back to learning.

Darrel, N0DBX

Andrew,

The 820 series has "phone patch in/out" jacks on the rear panel, you can use those. However,
I think that both jacks do not have a set level. You should be able to set the proper levels using the "mic" control for "patch in" and the "AF gain(volume) for "patch out" and your sound card/software.

Take a look at the schematic, you can see how they are wired.

Andrew, Joe's right. The 820's PHONE PATCH IN transmit audio level is controlled by the MIC gain and the PHONE PATCH OUT receive audio is controlled by the Volume control.

While there are a number of commercial sound card interface ready to use (plug and play), you can also build your own sound card interface at a significant savings. The Internet has plenty of schematics that show how to build your own sound card interface. Parts are available almost everywhere, Radio Shack, eBay, ham fest, Mouser, and DigiKey to name a few. You may have some or all of the parts in your junk box.

I built a PSK/RTTY/SSTV sound card interface and a CAT radio control interface on a single Radio Shack experimental PC board.

Also, understand that PSK, RTTY, SSTV, and other sound card modes are "100% duty cycle". This means there is RF output every time and as long as the transmitter is keyed and data is being sent. The TS-820 is not designed for 100% duty cycle transmissions. Short full power transmissions such as tune up into a 50 ohm dummy load can be tolerated but 2 minute or longer at full power PSK, RTTY, SSTV, and other sound card mode transmissions can easily over stress the final amplifier and power supply leading to possible damage to both. The fan on the rear panel is NOT designed to allow 100% duty cycle. The fan is designed to simply "move air" into and out of the final amplifier. Typical power output using sound card modes is between 20 and 30 watts with transmission times kept to a minimum with receiver periods to allow for transmitter cool down. PSK is a "low power" mode.

Mel,

K4eaa's new style of RL-1

Antenna relay(under metal shield by final amp board-(on the bottom of rig)

Brass shaft coupler(s)

Final cage repair kit

from nr6c.com: new sprockets

Known good pair of final amplifier tubes

Known good 12by7a driver

These are my choices. I'm sure this is going to create a very interesting "discussion"

K4eaa is only one supplier. A7oj, also has items you may want to look at: hybridrestore "dot"com

From: Mike W5RKL
Topic: 49624 Message: 49626

Hi Mel,

To answer your question, I must ask you a couple of questions.

1. What experience do you have in troubleshooting problems in electronic circuits?
2. What type of test equipment do you have (VTVM, DVM/DMM, frequency counter, signal generator, and oscilloscope) and level of experience using test equipment?
3. Do you have the operator AND service manuals for your TS-530? (available on my website, www.w5rkl.com for downloading)

Having spare parts on hand is not the only thing that's needed. If one is not able to properly and safely troubleshoot a problem using the appropriate test equipment, those spare parts are only good for collecting dust.

Steve,

L3 and L4 are the IF trap coils. Look at alignment step 15, page 39 in
the TS-530 service manual, for L3 and L4 adjustments.

Joe

Kens new relay is not the Ant TR relay for the TS530.

It is the replacement for what I call the Aux relay which is the Omron LZN4 4PDT flat pack relay.

This is the relay on the TS530S IF board and the TS830S AF board.

Agree should buy one.

The IF board relay is a must as previously mentioned. Problem with having spare tubes is if you don't rotate them through your radio, you could end up having a flashover when you change them out. I change mine around every 6 months. I'd go for a new ant relay, not cheap but necessary. Unless you know how to trouble shoot, no real point in having lots of spares. Have you changed out your HV caps? If not this is a must in my opinion, and if you do do it, change the IF board relay at the same time.

The 530 has a solder-in antenna relay (a pain to replace). If you replace that relay (none available that I could find), do a socket style relay conversion, to look like the 830.
I finally have the new plug-in, relay parts for my 530 and will install later this year.

If Steve doesnt have AF VTVM or O-scope can just listen to the 8.830mhz IF tone level in the speaker and adjust L3 and L4 for the lowest audio level. Can get a very deep null that you can barely hear.

80dB injection level = -33dBm or 5mv.

Mike, let me say thanks for the reply and I will try to answer your questions.

1. experience.... Some. I have been interested in electronics for many years, but only at the hobby level. That is to say that my work background is mechanical, retired machinist. In my early years as a ham I had Heathkit equipment that I kept aligned and repaired. I once brought a lightning struck micro wave back to life.
Also had a cousin that was in Civil Air Patrol. His FT-227R jumped frequency and I was able to fix it for him. Converted an old CB to 10 meters. I do not by any means consider myself an electronics whiz, but I can follow a schematic and figure out(most of the time) what things are suppose to happen. And too, I am not afraid to ask those more knowledgeable than myself for help.

2. equipment... At the present time I have the following, VTVM, DMM, and a 20MHz scope. I had a frequency counter at one time, but lost it in a flooded basement. The DMM has a freq counted built in, but only up to 7MHz. The scope....I must confess that I have had the scope for several years, but I am uncomfortable/unsure of how to use it. I realize that it is a important tool for RF work and at this time I have been watching W2AEW's YouTube videos and trying to learn more about the scope.

3. manuals... I received the operators manual when I bought the 530. I have also downloaded the manuals that you spoke of.

And to the others that responded to my post, I thank you and will explore your suggestions.

Mel... WD8NNL

Terry,

I agree with you. It was not my intention to indicate that Ken's replacement "RL-1" was a replacement for the T/R relay.

I should have used numbers to indicate change of thought or information..instead of triple spacing as I did.

From: Mike W5RKL
Topic: 49635 Message: 49636

Hi Cid,

Are you suggesting one of the following when you say:

"Turn down the drive"

Adjust the "DRIVE" control on the upper right corner of the front panel to reduce power output? The answer is "No!!!" You should NEVER adjust the "DRIVE" control to reduce power output.

Adjust the "CAR" control during TUNE/CW mode tune up to "preset" the RF output level? The answer is "No". The CAR control has no control over power output in sideband (USB/LSB), the CAR control is disabled in sideband modes.

There is a simple single transistor, 3 fixed resistors and one variable resistor (pot) that will accomplish the power reduction you are looking for. You will have to log onto Yahoo Groups using your web browser, use the following link to get to the group log in page:

https://login.yahoo.com/config/login?.done=http://groups.yahoo.com%2f&.src=ygrp&.intl=us

When the log in page comes up, enter your user name and password. Once logged in to Yahoo Groups, select the KENWOOD TS-520_820_530_830 group. When the main page comes up, click on "Files" (top middle of the screen below the search text box). When the Files page comes up scroll down and click on

"Kenwood Hybrid QRP circuit.pdf"

This simple circuit will allow you to reduce power output in sideband mode by applying a negative DC voltage to the transceiver's "RAL" and ground connection on the rear panels "REMOTE" 7 pin DIN socket.

Turning down the Drive won't work, what only
works for CW mode. You might want to explore
controlling the ALC though the back panel
accessory plug. There is a circuit that simply
takes a battery and a potentiometer that works
nice. Here is the simplest ALC mod.

http://www.vss.pl/mods.dk/ts520qrp.gif

There was also Kenwood Serice bullitiin #2 that
shows you to modify a TS-520 for novice 75 watt
operation. You could make the same change to work
on the 830. The service bullitin can be found
several places. Here it is on my web site, page #22.

http://www.wb4hfn.com/KENWOOD/Articles/SERVICE%20NOTES%20-%20ALL%20HYBRIDS.pdf

You can also just lower your mic gain, but you
would need a peak reading watt meter between the
amp and radio to see how many watts you were pumping into the AL-80.

Cid,

I would connect your exciter to the AL-80 amplifier as shown in the AL-80 manual, including connecting the amplifier's ALC connection to the exciter. Make the ALC adjustments called in the amplifier's manual, and operate the combination properly as outlined in the manuals, you should have no problems. Thoroughly read the manuals, exciter and amplifier, before you attempt to operate them together.

I have an Ameritron AL-811 (3 tube) amp. I don't throttle down the drive from my exciters (Heathkit HW-101, SB-100, Drake T4XB/C) I simply pay attention and operate the exciters and amplifier properly. I have been doing this for years and never experienced any problems or tube failure in the amplifier.

Cid,

The answer is yes.

The receive audio connection to the sound card interface is at the 830's speaker connection.
The transmit audio connection to the sound card interface is at the 830's microphone socket pin 1 and ground to pin 4.

Follow the sound card interface instruction manual settings and you should have no problem.

Also, I recommend you turn the speech processor OFF and adjust the MIC gain for no more than 25 watts output and keep transmission times short, 1 to 2 minutes at most.

The 830's ALC meter in sideband transmit should remain at "zero".

You can use DM-780 which contains the sound card digital mode software such as PSk31/64, RTTY, CW, and other modes, will work with most sound card interfaces and the TS-830.

HRD radio control features that allows the operator to change frequencies, change bands, see S meter, and display the radio's frequency, will not work with a TS-830.

Mark,

You can see if the CW filter is installed by removing the top cover of your 820. The CW filter, if installed, will be on the IF UNIT board which is on the "Left side" of the 820, 820 right side up, front panel facing you.

Do you have the TS-820 operator's manual? If not then I highly recommend you download it and spend time reading it. You can download the 820 operator's manual from my website

www.w5rkl.com

Click on the "Manuals Mods and Docs" link at the top of the page. When the Manuals page comes up, scroll down to the TS-820 section and click on the operator's manual link.

Looking at the IF UNIT board on the left of the 820, the CW filter will be a large square metal box soldered to the board. The picture below is the IF UNIT board in a TS-820. Notice the square BLUE labeled metal enclosure on the left of the board? That's the sideband filter. Directly above the sideband filter is where the CW filter will be "IF" the CW filter is installed. The board shown in the picture below does NOT have a CW filter installed!!

You will need to read page 34, section 6.4 ACCESSORIES, INSTALLING THE CW FILTER (YG-88C) paragraph, in the TS-820 operator's manual.

Based on what you have said, the receiver appears dead when the MODE switch is set to CW, I suspect the CW filter is NOT installed on the IF UNIT board in your TS-820.

Mark
Exactly what I would expect to happen. The pass band width is different for SSB and for CW. So, if you could hear a signal in the pass band of SSB then switched to CW the signal could be out of the CW pass band. That is what I would expect, and that's how it works on my TS-820 with out a CW filter. But what do I know?

Mark,

Congrats on your purchase. Mike-w5rkl, is essentially correct on the location of the CW filter.
If you can see the letters "CW" right above the "SSB crystal filter," the CW filter is NOT installed. The 820(S) will & should, receive CW fine even though no CW filter is present. IF the CW filter is present, it will slightly attenuate signals...especially if they are weak to start with...or the filter(if present) may be the problem. Tune around and find a good strong CW signal while in SSB mode...then switch to CW mode...can you still hear the signal? Remember..USB and LSB are on either side of the indicated frequency on the dial.....you may have to tune up or down slightly to get the CW signal. If not, your rig may have other problems.
As Mike suggested, get the Operating Manual, and read it, and read it some more. The 820S is a great rig...I've had mine now since about 1983...with no CW filter installed either!

Do you know the history of the rig? What is your knowledge base regarding electronics/radio and, do you have any diagnostic equipment?

Mark,

Congrats on your purchase. Mike-w5rkl, is essentially correct on the location of the CW filter.
If you can see the letters "CW" right above the "SSB crystal filter," the CW filter is NOT installed. The 820(S) will & should, receive CW fine even though no CW filter is present. IF the CW filter is present, it will slightly attenuate signals...especially if they are weak to start with...or the filter(if present) may be the problem. Tune around and find a good strong CW signal while in SSB mode...then switch to CW mode...can you still hear the signal? Remember..USB and LSB are on either side of the indicated frequency on the dial.....you may have to tune up or down slightly to get the CW signal. If not, your rig may have other problems.

Mark,

You can see if the CW filter is installed by removing the top cover of your 820. The CW filter, if installed, will be on the IF UNIT board which is on the "Left side" of the 820, 820 right side up, front panel facing you.

Do you have the TS-820 operator's manual? If not then I highly recommend you download it and spend time reading it. You can download the 820 operator's manual from my website

www.w5rkl.com

Click on the "Manuals Mods and Docs" link at the top of the page. When the Manuals page comes up, scroll down to the TS-820 section and click on the operator's manual link.

Looking at the IF UNIT board on the left of the 820, the CW filter will be a large square metal box soldered to the board. The picture below is the IF UNIT board in a TS-820. Notice the square BLUE labeled metal enclosure on the left of the board? That's the sideband filter. Directly above the sideband filter is where the CW filter will be "IF" the CW filter is installed. The board shown in the picture below does NOT have a CW filter installed!!

You will need to read page 34, section 6.4 ACCESSORIES, INSTALLING THE CW FILTER (YG-88C) paragraph, in the TS-820 operator's manual.

Based on what you have said, the receiver appears dead when the MODE switch is set to CW, I suspect the CW filter is NOT installed on the IF UNIT board in your TS-820.

Hi to All,

Great comments! Thanks to all who replied...

I checked and I do have a CW filter. Yes, it somewhat attenuates the signal from SSB. Good news... I was playing around and I tried the IF shift and I was able to hear the signal so I assume that I would be able to operate there. I did not try to break in as yet I am way too slow at CW.

Some history... I got my license back in April of this year, but just got my first HF rig last month. I picked it up locally (Chicago area) from a guy in the area whose friend passed away. The friend's widow gave it to him and I bought it from him. It seems to be in very good working condition other than the flicker of the frequency display. I got manuals with it and I am reading it and learning the knobs on the 820S. I am also learning CW and it is going slooooly, but I am getting there. I bought an old J-38 key on ebay and I'm trying to get the send part. I have only been trying to read. I also just bought a used GAP Titan DX antenna that seems to be working fine. I have yet to check the SWR, but they claim no tuner is needed. I have made a few contacts on 20m and 40m.

As for me, I have a background in electronics, but it has been a long time since I used it. I have a cheap VM and also I have an oscilloscope in the crawl space downstairs, but I don't think it has any leads/probes.

This sounds like a really cool rig made back when I was in high school. I hope I can keep it going another ~35 years.

Mark,

The CW filter is suppose to provide a much narrow bandpass for the IF signal to travel through. Therefore, the CW signal is going to sound different with the MODE switch set to CW with the CW filter installed, than the CW signal sound with the MODE switch set to USB Or LSB.

The IF Shift control should be normally set to 12 o'clock, the knob line pointing straight up. The IF SHIFT has a detent at 12 o'clock, you should feel it as you rotate either side of 12 o'clock.

You didn't say if you have the operator's manual for the TS-820 or not. If you don't have it you can download it free from my website

www.w5rkl.com

Click on Manuals, Mods and Docs link at the top of the page. When the manual page comes up, scroll down the TS-820/TS-820S section and download the operator's manual then spend time reading the manual so you understand what each control is for and how to use those controls properly and safely.

49652. HYBRID NET UPDATE (Sept 14, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-14 20:54:52 UTC
From: Mark Gilger
Topic: 49652 Message: 49652

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
Â
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.Â

The Saturday net was run by me, WB0IQK. There
were 18 stations checking in under good band
conditions. We had the following number of radios checking in.

3 running TS-520(x)

2 running TS-530(x)

1 running TS-820(x)

3 running TS-830S

0 running TS-511

0 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-940S with an L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
13 stations checking in under good band
conditions. We had the following number of radios checking in.

3 running TS-520(x)

2 running TS-530(x)

2 running TS-820(x)

2 running TS-830S

0 running TS-511

2 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-820s twins (TS-820S + R820).

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940â□□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012Â Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
November 2013, Saturdayâ□□s net total = 94, Sundayâ□□s total = 85
December 2013, Saturdayâ□□s net total = 87, Sundayâ□□s total = 103
January 2014, Saturdayâ□□s net total = 71, Sundayâ□□s total = 82
February 2014, Saturdayâ□□s net total = 80, Sundayâ□□s total = 85
March 2014, Saturdayâ□□s net total = 82, Sundayâ□□s total = 73
April 2014, Saturdayâ□□s net total = 64, Sundayâ□□s total =43
May 2014, Saturdayâ□□s net total = 66, Sundayâ□□s total = 35
June 2014, Saturdayâ□□s net total = 43, Sundayâ□□s total = 59
July 2014, Saturdayâ□□s net total = 24, Sundayâ□□s total = 46
August 2014, Saturdayâ□□s net total = 62, Sundayâ□□s total = 53
September 2014, Saturday's net total = 31, Sunday's total = 13 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

49653. How to set VFO-820 VFO endpoints

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-15 17:16:36 UTC
From: Chris Kepus
Topic: 49653 Message: 49653

Hey Kenwoodies,

I'm working on a VFO-820 that is cookin' along quite well with a very minor exception. It's off by a few Khz at the endpoints (as seen on a frequency counter - can't really see it on the dial markings). I've been through the 820 (S) service manual and the VFO-820 manual and list archives and the usual internet searches but no joy re: adjusting endpoints. Then it occurs to me. if I'm using either a 820 or 820S, I'm looking at a digital readout which, according to the schematic, is showing the VFO-820 frequency. Correct? Hence, it doesn't matter a whit if there is a slight difference when I am playing with the VFO-820 standalone and get the results mentioned above. I was about to relax and forget about this but being a Virgo is a real handicap sometimes.sigh.

So, here I am taking up bandwidth seeking affirmation. Am I right in my conclusion (it doesn't matter)..or not?

PS: Is there a way to adjust the endpoints.even if it doesn't matter?

PPS: This VFO-820 is surplus to my needs. If you are wishing you had a really nice one, send me a private message and we'll talk.

Thanks.

Chris

Chris,

Look on Pg 48 of the 820(S) service manual, Section 2-11 "VFO adjustment."

I would also check for proper calibration of the DG-1..same page..Section 3 and frequencies listed in the table on Pg 45 Section 2-1(3)

Chris,

You said,

"/*I'm looking at a digital readout which, according to the schematic,
is showing the VFO-820 frequency.*//*C*//*orrect?*/"

No, not true.

The digital display is showing the actual operating frequency. The VFOs,
whether internal or external, operate over a frequency range from
5.500Mhz to 5.000Mhz. This is clearly shown on the TS-820S block diagram
on pages 5 and 24 in the 820 service manual.

49656. TS-530s issues

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-15 18:12:03 UTC
From: john
Topic: 49656 Message: 49656

My TS-530s was working ok when just RXing (still no antenna) The setup is scanner aerial into the AT-230 ATU and then into the TS.

While tuning around the bands I was getting stations OK.

Unplugged the set and took it to the local radio club so they could show me how to setup the radio.

Setup the radio at the club and they started setting up the radio for TXing ATU set to Dummy and proceeded to start setting the load etc, but this didn't show much in the way of output on the ATU.

A bit more fiddling and then the dummy load was connected (it was thought that the ATU came with a Dummy load built-in). Eventually after some playing around it was decided that three valves might be at fault. Luckily someone in the club has a set I can have and also has a valve tester.

While trying to get the radio setup we noticed that if the ATU or Dummy load was connected to the main antenna input on the radio (not via ATU) the needle would bounce around as if there was a bad connection.

So, I took the radio home and set it up on my desk as it was before. I also noticed that when tuning around the bands, the needle will bounce around as if there is a bad connection. So I tried without using the ATU and connecting the scanner antenna to the back of the radio and the same was observed. With nothing connected via the antenna socket the radio behaves and the needle stays stationary when tuning around.

I am going to remove the three valves and take them to the club for the next meet and pick up the new valves.

Any thoughts people?

Thanks

John , M6JPE

UK.

John,

The Kenwood AT-230 tuner does not have a built in 50 ohm dummy load.

Before you waste money on new driver and final tubes, did you check the rear panel 530's "SG" switch to ensure it's in the "ON" position? Handling the 530 can easily result in that switch be moved to the OFF position which will result in no transmit RF output during tuning or operating of the 530.

Using a scanner antenna is not a good idea. The scanner antenna is designed for VHF work and the 530 is designed to operate on HF frequencies. The AT-230 is designed to provide a match to amateur band antennas between 1.8Mhz and 30Mhz, not VHF frequencies (see the AT-230 manual for details).

Why not build a simple HF dipole antenna, you will have much better luck with the correct antenna than using a VHF scanner antenna. Use the formula

468 / <freq in Mhz>

to determine the initial starting point length of the antenna before trimming each end the same amount for lowest SWR.

For example, a 40 meter dipole will have an end to end length of approximately 66 feet at 7.1Mhz (468 / 7.1 = 65.915)

This antenna can be fed with 50 or 75 ohm coax.

I forgot to mention. The SG switch only affects the final amplifier during transmit. The receive signal does NOT travel/flow through the transmitter's driver and final amplifier stages. Wasting money buy/obtaining NOS driver and final tubes because the receive is poor will not improve the receive signals.

Topic: 49656 Message: 49659

Hi Mike
Thanks the reply. The tubes I am getting a FOC which is nice.
I did check the SG switch and its on the ON position
We did suss that the ATU Dummy setting is just for attaching the Dummy load to.

At the mo the scanner aerial (does cover the HF band) is just for RX only as I need to get a microphone for it, and the other antenna I have been using is a length of wire in the loft, which both have worked OK recently.

Cheers

John

First, you need a better antenna for the HF band .Try cleaning the controls, switches and see if that cures the problms.

Topic: 49653 Message: 49661

I don't kow if the VFO has fine trimmers and padders for band limit alignment.
When I was running my basic TS520, (strictly analog dial) I just had to remember to recalibrate the mechanical dial with the xtal calibration signal when I moved from the bottom of a band to the middle . I RARELY EVER WENT TO THE TOP OF A BAND. but it was easy to use the calibrator signal to get right on the marks.

My radio is Ham Radio...CW is Real Radio

Chris,

You said,

"I'm looking at a digital readout which, according to the schematic, is showing the VFO-820 frequency.Correct?"

No, not true.

The digital display is showing the actual operating frequency. The VFOs, whether internal or external, operate over a frequency range from 5.500Mhz to 5.000Mhz. This is clearly shown on the TS-820S block diagram on pages 5 and 24 in the 820 service manual.

From: ckepus@...
Topic: 49653 Message: 49663

Thanks for the quick replies from Joe, Mike, and John.

Joe, your reference to the SM p 48 covers EP adj for the TS-820 VFO, and does not reference this procedure to be applicable to the external VFO-820 which is covered in the same SM on pgs.71 and 72.

The specifics on the adjustment on p.48 seem confusing (in error??) as follows: the manual directs the reader to adjust TC1 and L1 and refers the reader to Figs. 30 and 31. While there is a TC1 shown in Fig 30 (FIX - VOX unit), there is no L1 shown in Fig 31. In Fig 29 (Marker), there is both a TC! and a L1: Please note that the FIX - VOX board X50-1350-00 p.59 has its own TC1 and L1 but they are associated with Channel 1 , not the VFO.

For those who have been there, done that, on which board(s) are the correct VFO TC1 and L1 located?

As many of you may know, the schematic and board number for the VFO-820 VFO board is identical the schematic and board number for the VFO board in the 820 "mother ship". Since there is no board component layout provided on p 71 or 72 for the VFO-820, I'll make the assumption that it is identical to the VFO board component layout in the "mother ship". Which then brings us back to the question: Where are TC1 and L1 for the VFO-820? Only two possibilities: They're on a different board in the VFO-820 enclosure.which are not shown anywhere..OR.. the VFO-820 circuitry utilizes, by virtue of some trick switching scheme, the same TC1 and L1 that the "mother ship" VFO uses...wherever TC1 and L1 may be.

Does anyone know if this is the way things work and where TC1 and L1 really reside?

Mike: You said: "The digital display is showing the actual operating frequency. The VFOs, whether internal or external, operate over a frequency range from 5.500Mhz to 5.000Mhz. This is clearly shown on the TS-820S block diagram on pages 5 and 24 in the 820 service manual."

You're correct. And I actually know all that. I just threw everyone off by failing to write what was in my brain.

My brain said: When the switch on the "mother ship" is thrown to engage the external VFO, the processing of the VFO-820 signal coming into the "mother ship" results in the VFO-820 range of 5.5 to 5.0 Mhz being processed and translated to show on the "mother ship" digital readout as the actual operating frequency so no mental gymnastics are required on the part of the operator. My somewhat unusual and rhetorical question is: That being the case, why would anyone but a Virgo worry about the analog dial on the VFO-820 being off by 2 KHz (or less)?? What, me worry?

To repeat: Does anyone know where "mother ship" TC1 and L1 really reside and are they utilized by the VFO-820 when the external VFO is engaged?

49664. Thank you

Topic: 49653 Message: 49665

Chris,I agree that the referenced figure is rather poor. I should have been MORE specific.

The remote VFO-820's VFO and the rigs VFO are exactly the same. L-1 and TC-1 are under the silver tape on the top side of the VFO metal shield. L-1 is accessed through the rear hole and TC-1 is at the front. NOTE: L-1 has VERY strong white thread lock. IF you do not remove the thread lock before you try and adjust the shaft..you will break off the screwdriver slot ears. The shaft is made of brass and doesn't take kindly to force!

You should be able to make your adjustment(s) on the remote VFO (if so desired), just by selecting it from the function switch

As you have noticed...the service manual has errors of all kinds.

73 Joe

Topic: 49653 Message: 49666

Chris,

You said

"/*My brain said: When the switch on the "mother ship" is thrown to engage the external VFO, the processing of the VFO-820 signal coming into the "mother ship" results in the VFO-820 range of 5.5 to 5.0 Mhz being processed and translated to show on the "mother ship" digital readout as the actual operating frequency so no mental gymnastics are required on the part of the operator. *//*
*/
There is no switch on the TS-820 or TS-820S ("mother ship") that "engages the external VFO". The remote VFO-820's FUNCTION switch determines which VFO, internal or external, is used to control transmit and receive frequencies. Split operation, where one VFO controls transmit and the other VFO controls receive, on the same band, is determined by the setting of the remote VFO-520 or VFO-820's FUNCTION switch.

Setting the remote VFO-820's FUNCTION switch to OFF causes the TS-820/TS-820S internal VFO the sole frequency controlling source.

Normal VFO operation with or without a remote VFO-520 or VFO-820, requires the TS-820/TS-820S FUNCTION switch to be set to "VFO".

FIX settings of the TS-820/TS-820S FUNCTION switch is similar but not the same as using remote VFO-520 or VFO-820 and internal VFOs to control frequency of the transceiver.

TS-820/TS-820S FUNCTION switch settings

VFO = Internal or remote VFO-520 or VFO-820 controls the transceiver's transmit and receive frquency
VFO R = Internal or remote VFO-520 or VFO-820 controls the transceiver's "receive" frequency but a crystal controls the TS-820/TS-820S "transmit" frequency
FIX R = Internal or remote VFO-520 or VFO-820 controls the transceiver's "transmit" frequency but a crystal controls the TS-820/TS-820S "receive" frequency
FIX = a crystal controls the TS-820/TS-820S transmit AND receive frequency, internal and remote VFO-520 or VFO-820's are "disabled"

All of these features are discussed in the operator's manual.

You will notice I included the "VFO-520" as a possible remote VFO that can be used with the TS-820/TS-820S. The VFO-520 is the same VFO and is wired the same through the VFO connecting cable as the VFO-820.

Therefore, the VFO-520 or VFO-820 will work, plug and play, with the TS-820/TS-820S and vice verse, the VFO-820 or VFO-520 will work, plug and play, with any of the 3 TS-520 series transceivers.

49667. TS820S Frequency Shift and Drive

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-16 05:00:40 UTC
From: light316@...
Topic: 49667 Message: 49667

Hello All,

I have the TS820S and I am noticing frequency jump/shift of 1.5Khz. It was on the 40m band today but I also noticed on 20m as well. I also see a bit of drift. I saw/heard it at the low end of the band listening to CW tones changing over time.

I have read that cleaning the contacts of the VFO would help so I plan to purchase some Deoxit soon. Any other thoughts?

73s, Mark, K9MVC

Mark,

The TS-820 and TS-820S, both are the same transceiver minus the digital display in the TS-820, will drift. The STABILITY specifications for both transceivers is listed in the TS-820/TS-820S operator's manual's Specification's page. Typical drift is 100Hz during the first 30 minutes warm up and 1Khz during the first hour warm up.

I don't know if you are aware but the TS-820 internal and VFO-820 external VFOs are both analog VFO which means they have a variable capacitor and coil. Neither of the TS-820 internal or VFO-820 external VFOs are digital VFO.

Mark,

Is this something new on a rig you have had for sometime? Some "drift" is how much? IF the VFO drifts +/- 1khz during approx 1 hour period after 1 minute warm-up....that is within Kenwood specs for this rig...100Hz during any 30 minute period after warm-up..is within specs.

"jumping/shifting" of the indicated frequency when rotating the main VFO dial...usually indicates some "crud" on the VFO's wiper arm. The jumps will be observed on ALL bands...in just about the same area. It is not difficult to clean the offending part...just need to take your time, and there are several ways to clean the wiper arm.

DeOxit is fine...get some "canned air" while your at it. You can find it at computer stores, Walmart, and other places. You use it to blow off/out the crud dissolved by the DeOxit..and to dry it out.

Topic: 49667 Message: 49670

Hi Mike,

Thanks for the info. Yes, it makes sense that it is an analog VFO. The drift I noticed was after it was on for an hour or more and it was quite large. It was shifting down (or up, I can't remember exactly) at about 100hz per minute. It is the instantaneous jump in frequency of ~1.5Khz that would shift up, then back down after 10 seconds or more.

Thanks,
Mark

49671. Re: [TS-520_820_530_830] TS820S Frequency Shift and Drive

Hey Joe,

Thanks for the notes. The jumps are across bands as you noted. I am not sure it is the same portion of the band, but expect it might be. It is always where you do not want it to be. :) The drift was not noticeable that much until I was down in the CW area. It was shifting the code sound.

This is my first rig and I have had it about a month. It didn't seem to shift back when I first got it, then again maybe I did not notice it since I am learning. My guess it was, but I thought it was the flaky display.

I need to get some Deoxit and canned air. Plenty of hot air, but that will not help. :)

Thanks! 73

Mark,

Glad to help. The problem you arfe having with the frequency jumping around is very common. It can also effect the other Kenwood hybrid series that use similar VFOs. The VFO in the remote VFO is rather easy to do...the one in the rig is a bit more involved.
Gordon-n6wk(sk)
has some pictures of what you have to do to. Go to: N^WK "dot" com scroll down until you find "TS-820 VFO Service Proceedure." It's really not that hard. Or you can use a fine pir of needle-nose pliers, or an angle phillips screw driver and remove the rear most screw from the cover on the side of the VFO...and just loosen the front one. Swivel cover out of the way...and with BRIGHT LIGHT look towards the rear of the VFO...you'll see the VFO shaft and a piece of spring metal...that's what you have to clean with the DeOxit and canned air. Give it a small spray and rotate through lock to lock several times..spray again...rotate again...blow out with canned air. Before you put it all back together...check for proper operation..if it all now works...button it up. You may even solve your drift problem too.

NOTE: do the above with rig unplugged from power!

> you'll see the VFO shaft and a piece of spring metal...that's what you have to clean with the DeOxit and canned air.

From previous conversations on this list about this very item of hardware by at least two of the better (professional) hybrid repair people, it is probably a good idea for someone (even if he is NOT one of the top repair people here - and of course by that I mean ME) to once again mention that you should

ONLY CLEAN THE CONTACT WIPER SPRING AND THE SHAFT,
AND NOT TRY TO BEND OR MANIPULATE THE WIPER SPRING
TO BE TIGHTER AGAINST THE CAPACITOR SHAFT

That bit of metal is rather fragile for one thing, and it is springy by its very nature. If you try to tweak it, you risk breaking it for one thing, and you will almost certainly LOOSEN it and make it less effectively contact the shaft.

Don't bend it, squeeze it, pry on it, or do anything to it except clean it and the shaft it touches. Be careful when you're in there so as not to make a minor problem worse.

Well, if this was a real list server managing a real list instead of a piece of crap that the yahooligans recently modified (again) to be even worse than it was before, I can't be sure that ANYONE can search for things and expect to get the same answer back twice, or the correct answer even once.

I'll give it a go and see what I can turn up, and I'll tell you how I did it if I get anywhere, fair enough? It will take a while, maybe ten or fifteen minutes after this message is sent, for the followup with what I can find, if anything, and those instructions for how. Is that acceptable? Best I can do today, I'm pretty much an invalid at the moment, the arthritis that is my normal nemesis has hit my lower spine and I'm flat on my back for the a while, maybe for the foreseeable future.

(If it is permanent, I'm not going to screw up the rest of my wife's life with changing my diapers. I'll be moving to the V.A. nursing home ASAP if it is. Yes, life at this point in time, SUCKS.)

I do hate Yahoo and all their ilk.

I have been running mail and web and file servers for as long as they have been in existence. Now I do it only as a hobby, being retired and all that, but I still remember how. Almost every facet of the "new" yahoo interface and software is a roach motel. Poor design, no attention paid to proper user interfacing, no integrity in the database, they did NOTHING correctly.

I -wish- I could convince the owners of this list to move it about ANYWHERE else, onto a MailMan or MajorDomo or other similar mailing list manager, and just have a proper web page. I could host the thing myself out of my basement, and wouldn't even charge them for the service, it just sits there most of the time, anyway. They would have to get someone to write the database connection web page to store files, photos, and downloadable stuff. The MailMan list manager I run already does archives and searching of them really well.

Mark and others,

To find out IF your problem has been discussed before...which it most likely has..go this groups "Home Page." One the left side of the page, right under the picture of the great KW station, click on "conversations." In the long box right above, enter you criteria...ie "cleaning VFO," or "VFO drift." You will get numerous "conversations (posts)" that have your key words. I entered: "cleaning VFO" and got back approx. 30 posts...including some with frequency drift mentioned. The more generic you are, the more "conversations" you'll get back...I mean possibly in the hundreds. It helps to be specific. Also, Click on the "files" area...lot's of info there too.

I have no control over Yahoo...I just have to work with it/them as you do...and it gets rather tedious.

Topic: 49677 Message: 49677

I know this is not Kenwood related and I apologize for that but since I am having no luck elsewhere, I thought maybe some one on the group may have an HW-101 that doesn't work or an HW-101 parts chassis with the LMO intact or just the LMO laying around collecting dust they would part with. I don't need an HW-100 parts chassis nor the HW-100 LMO, I already have one. I also don't need the TRW Tube LMO from the SB-100/101 or SB-300/301 either, I already have 2 of those. I need an HW-101 LMO with dial and dial hardware including the 2 Jackson Drives. If you happen to have these item(s) and you would part it at a "reasonable" price, not a month's rent, let me know off group.

There is a "Help" link on any Yahoo group main page. It's the "?" to the right of "Management. Simply click on it and when the Help page comes up, enter the topic

"search"

in the search text box and click the "Help Search" button at the top of the page.

You can only search one Yahoo Group at a time and you must be logged into Yahoo Groups to perform any search.

If you are using an e-mail client such as "Thunderbird", you can search your email for topics of this nature. The search text box is located at the upper right of the page, just enter the search topic and click the magnifying glass or press enter.

Hello All,

I ordered some DeOxit to clean VFO but still waiting for it to get here.

New info on the frequency jumping around...
I found that the frequency is still bouncing around, but I found that if I use RIT, it is stable on the receive end. I also noticed that when I enable RIT, it should be near the frequency I start at, but now recently I have to shift way negative to get the same frequency. I read in the service manual how to adjust this, but just last week it seemed pretty close to zeroed.

Your thoughts?

Thanks,
Mark, K9MVC

49684. Clearance on my Hybrid Parts...

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-18 15:25:16 UTC
From: ke5ftf@...
Topic: 49684 Message: 49684

I have not had a buyer for all my Kenwood Hybrid parts...

I do need to sell it all so will offer lower pricing here on the Kenwood Hybrid Group...

All the Kenwood Hybrid (520 to 830S) parts are clean & working condition...

Smaller parts such as Knobs & Control Pots (weights of 1 to 16 ounces) will be

mailed by Priority Mail box with Tracking & Insurance...($6.40)...

Heavier parts such as a Transformer (8 lbs. ea.) will be mailed by

Priority Medium Flat Rate ($12.65)...
****
My first offering is the two Power Transformers for the 520 to the 830S

(you pick as I have many)...

Two (2) Power Transformers ...

Packed & mailed by Priority Mail Medium Flat Rate w/Tracking ($12.65 cost)....
Total.....$82.65... (Normally $112.65)...

Note... I can mix the transformers like a 520 & an 830S....

Add $3.00 for a PayPal payment OR I can take a Personal Check or a PMO...

Thanks
Bob

Mark,

Before you start adjusting circuits, wait until you have cleaned the VFO flexible connection and the RIT pot FIRST. You may find you won't have to make any adjustments.

If you have not yet purchased canned air, go to Walmart and purchase at least 2 cans in the TV/Cell phone department. When using canned air, do NOT turn the can upside down and do NOT shake the can!!

Read ALL warnings on the DeoXit D5 and canned air cans!!! If you purchased the flammable D5 cleaner, you MUST wait at least 2 minutes after completing the cleaning process before powering up the radio/equipment. This is clearly stated on the D5 can!!

Also, pay attention and use only enough cleaner to do the job. Do NOT soak the area or pot with cleaner. Use canned air after cleaning the VFO and RIT pot to remove any/all cleaner and dirt residue. Wait at least 2 minutes before powering up the equipment. The 2 minute wait is clearly stated on the D5's can.

Hi Mike and Wes,

Thanks for the reminder. I plan to use canned air. I assume I can get that locally.
I also do not need a fire in my house, so I will let it go a while and vent out the fumes.
I will not tune further until I get this fixed up better.

Thanks,
Mark

From: john
Topic: 49656 Message: 49700

The issue appears to be resolved. I have replaced the tubes with new tested OK ones - but this did not cure the needle bouncing around while tuning the radio.
What did appear to fix it was, the previous owner had made a mod to allow 28mhz transvertor (I think to allow TXing on 2m band) and this switch was on so turned off this switch and normal service has been resumed.

Cheers

49701. TS-530S antenna tuner

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-19 21:03:09 UTC
From: yams280@...
Topic: 49701 Message: 49701

Hi Guys,

I just got a TS-5230S and I am looking for an antenna tuner. I know the AT-230 is the one but, I have been getting out-bidded on Ebay and I am not sure of the conditions of those units. So my question is could I use one of the MFJ models with my TS-530S? Also, if HAMs on this list can mention the tuner they use if it is not an AT-230?

Thanks,

Travis,

73

Travis,

My question to you is, why do you think you need a tuner?

To answer your questions, can you use an MFJ tuner with a Kenwood TS-530? Yes, RF is RF whether it comes from a Kenwood, Heathkit, Hallicrafters, or Collins transmitter. You do not have to use a specific brand of tuner such as a Kenwood tuner with a Kenwood transceiver. You can use an MFJ, Drake, Johnson, or even an homebrew tuner with your Kenwood TS-530.

There are antennas that do not require a tuner. For example, a Hustler 5BTV 5 band vertical doesn't require a tuner. If the vertical antenna is mounted above ground then radials for each band will be require but if the vertical is ground mounted, radials are not always required. I have operated HF using a Huster 5BTV vertical with the 80 meter resonator removed making it a 4BTV vertical, mounted on the top of a chain link fence in the back yard without any radials and NO tuner!!

A simple dipole either mounted horizontal or in an inverted vee fashion does not require a tuner.

A multi element yagi such as a Mosley TA-33, does NOT require a tuner.

A few examples of antennas that require a tuner are

Long wire
G5RV
Loop antennas
Lazy H
Sturba Curtain

There are many other types of antennas, some require tuners while others do not. The only antenna I have used that required a tuner is the G5RV and I used a Drake MN-2000 tuner with Kenwood, Heathkit, and Drake transmitters.

The ARRL antenna handbook is an excellent reference/study book. I recommend you purchase one and spend some time studying antennas. You can make a lot of antennas yourself, saving you a lot of money.

Travis,

You can use any tuner you choose, as long as it can handle the RF output...I have not used an MFJ tuner myself..others have though. I try and not endorse products...kinda keeps one out of trouble..in case something bad happened....hihi. You can mention/talk just about any Kenwood or other ham radio related items/topics...tuners included...as long as it conforms to the groups rules/policies which were sent to you automatically upon membership acceptance...or as you did just ask.

Also, you should get yourself(or build it) a dummy load also capable of handling a minimum of 100W for about 1-2 minutes...or longer.

And last but not least..remember to also use your call(if any) with your name when posting

Hi Mike,

I forgot to mention that I am planing on building a HexBeam for DX. My options will most likely broaden once I read the ARRL antenna handbook.

Greetings group,

Some of you may have missed Mike-w5rkl's msg earlier about the derogatory and inflammatory accusation(s) regarding Bob Mansker-ke5ftf being CLOSED. Many here have dealt with Bob, myself included, and have had no problems.
If you would like to continue this discussion,please do so off-list.

So, let's consider this topic CLOSED.... and see what other goodies Bob is going to put up for sale

We know return you to our regular programming

I just go a TOP SCORE. A Kenwood TS 520S, DG5, SP520, MC50, 2 sets of valves and heaps of manuals, both service and owners for a real song. At the moment I'm one very happy chappy. Talk about right time right place. I'm going to put it next to my TS 520SE and use it for 80 meters as I use the SE for 40 meters.
My mate was glad to see it go to a good home where it will be used.

Travis, the matching AT-230 is nice looking, but, any tuner will work. I'm using an LDG auto-tuner ... no special cables, and, works splendidly at 1/2 the price.

Hi: I agree with this statement, but with some additions: I believe that MANUAL tuners generally have greater range and flexibility over auto tuners. On eBay, the advertisers for certain wire antennas state that their advertised frequency coverage is for manual tuners, that auto tuners may not cover all of the bands.

Secondly, again generally, certain brands, such as MFJ, don't have the quality reputation of other brands, or, some of the products may not be as well made as others within the product line..

Thirdly, not all tuners provide the same antenna options other than coax: single wire, balanced twin lead, built-in balun, etc. Some of the manual tuners have roller inductors, allowing complete variable operation, while others use tapped coils with a bandswitch. Some tuners, like the '230 have SWR and Power Meters built-in. Some have dummy loads.

Finally, there is the power handling capability, usually 100/200 watts or one or more KWs !

There are also differences in tuner design, such as "T" "L" and others.

If you scroll through the "Antenna Tuner" section on eBay, you will start to see the number of variations that there are... Lately, all prices for items associated with the TS-830s have gone through the roof!

73,

Bob / WA2JAJ

Thanks to Ken K4EAA, I have all of the lights so I can for the first time in years see the dials on my TS-520, and the VFO-520, not only that but also for the first time in years there will be screws in every hole.

One thing I have also wondered about the VFO-520 is it's feet. it has a pair of conventional hard rubber feet up front, and in the back single folded piece of metal. is this bracket/foot supposed to hook into something. Ken has replacement feet and I just may get some and replace that bracket with a pair of feet to match the front.

I have run a Dentron Super tuner for many years, several decades in fact. It is a great tuner. what you have to watch for if you run into one is it does not take kindly to hot switching, if you can examine the wafer switch before a purchase that is a good idea. Always go inside and retouch the center conductor soldering job on the SO-239's sometime they develop cold solder joints so this is a pre-emptive move.. The big difficultly this tuner has and it is strictly an age issue is the plastic stand offs for the air variable capacitors, the tapped inductor, and the 4 plastic spreaders for the tapped inductor they get very brittle with age. the plastic stand off's for the air variables, and the inductor you can just make out of a good piece polycarbonate. The 4 spreaders for the tapped inductor are also easy to deal with, just get some " Seal-All" at the hardware store or automotive parts store. Simply run a bead of it on top and a little on either side of the present plastic spreaders. It dries clear flexible, fixes any cracks and binds up everything else so there is no chance for the inductor coil to short out.. I recall paying $45 dollars for mine, but that was over 30 years ago. It does not have it's own SWR/Watt meters but in tuners of this age the meters are not worth a damn anyway you are better off with a modern stand alone meter set anyway.

Ken,

I've never seen any discussion in theVFO-520 or VFO-820 about the rear "L Shape feet" other than it can be removed. I suspect you could find some hard rubber feet to replace that "L Shape Foot", I see extended feet sold on eBay quite often, look for Heathkit feet. There's a Heathkit SB-401 rise feet ad on eBay, #380997883844. The auction has the smaller rear feet with screws and the plastic riser feet and smaller hard rubber feet with screws. There are other feet ads just have a look to see what you might be interested in. You can also use wooden dowels cut to the size you need then drill a small hole in one end and use a small wooden screw to hold the wooden dowel to the cabinet. Cut the dowel slightly shorter than necessary then attach a peal and stick felt foot cut to the size of the dowel on the end that rests on the table. This change can be easily removed and no drilling holes to the cabinet is required, only the small holes in the wooden dowel.

The bent bracket at the rear of the VFO supports the rear of the cabinet.

Kenwood supplied two rubber feet for the front of the cabinet. They also supplied a plastic extension that raise the front of the cabinet an additional 5/8". The plastic extensions screwed into the cabinet and the rubber feet screwed into the plastic extension.

Date: 2014-09-21 19:11:23 UTC
From: Mark Gilger
Topic: 49717 Message: 49717

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.Â

There was no net Saturday.

The Sunday net was run by me, WB0IQK. There were
10 stations checking in under good band
conditions. We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-940S & Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940â□□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit

and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
November 2013, Saturday's net total = 94, Sunday's total = 85
December 2013, Saturday's net total = 87, Sunday's total = 103
January 2014, Saturday's net total = 71, Sunday's total = 82
February 2014, Saturday's net total = 80, Sunday's total = 85
March 2014, Saturday's net total = 82, Sunday's Total = 73
April 2014, Saturday's net total = 64, Sunday's total =43
May 2014, Saturday's net total = 66, Sunday's total = 35
June 2014, Saturday's net total = 43, Sunday's total = 59
July 2014, Saturday's net total = 24, Sunday's total = 46
August 2014, Saturday's net total = 62, Sunday's total = 53
September 2014, Saturday's net total = 31, Sunday's total = 23 (Month to date)

Hello, I am new to the group and to ham radio. I've had my ticket a short time now and I'm working on obtaining my general. I have picked up a TS-820S that needs some help. It does not receive (just a barely audible hum), or transmit. (holes in the final tubes may be a problem there, I have some great pics of them) I have recapped it recently, and I'm confident the cap replacement is fine, although not verified more than just power up. I have schematics and some electronics experience. I'm looking for instruction on where to start in the diagnosis process.

...yes, it has the VFO plug installed. (pins 8/9 shorted)
I have replaced the tubes and the common parts that fail in the receive section. I left the SG switch off and have not tried to transmit since recap. no bias adjustment or neutralization has been done yet. I'm focusing on receive first. I realize I'm going to have to learn to read the schematics and test voltages. I just need an Idea on the process to start.

This rig had receive before I took delivery but a digital display problem the seller tried to correct. when I bought it, the display was ok but there was no sound. I did find a board not fully connected and a couple of shorted wires as well. I'm still unable to get sound however. I will start by tracing the previously shorted wires in the mean time.

Thanks, Dan
KD8ZAZ

I've decided to reopen this case as well over a year ago, I resorted to a work around - using a separate SWR/Power meter inline with the tuner. While this has been functional I'd rather de clutter the desk if possible - or make room for something else!

Both power & SWR meter readings differ from my reference meter - A Diamond SX-100 which my modern radio tends to agree with also in it's inbuilt power/swr indications.

The user manual makes reference to variable resistors and that they shouldn't be touched. Instead return unit to Kenwood. It would be easy enough to mess about with these to approximate readings but is there a more accurate way to setting the meter up accurately - without a full test lab?

The other matter is the red SWR scale is rather faded having being exposed at some point in it's life to too much sun I expect. Chances of picking up a meter from a parts unit is highly unlikely. I'm wondering if getting a high res photo of a good meter, printing this on label paper and sticking it over the faded meter face is better than tracing over existing scale & numerals. Any suggestions?

The metal rear support has two positions. Low to match the lower front height when you use just the rubber feet and the high position to match the front height when you use both the plastic spacer and the rubber feet. I like having my cabinets higher in the front so I set the rear bracket to the low position and use the extensions in the front.

Chris,

I don't know what is wrong with your meter but most of them employ a simple diode rectifier and trimpots to adjust the meter for full scale on each range. They are certainly not precision instruments but give you a good indication of your TX power.

You said you have a reference meter which I assume you trust. You can use it as the calibration source for your meter as long as you know it is accurate - +- a few percent is normal. You also need a good dummy load that present 50 ohms to the TX. Remember that a load that is not 50 ohms will affect your power reading somewhat.

Put the two power meters in series from your transmitter to the load. Key up the TX (constant carrier) and put out enough power that your meters read at least more than 70% of full scale preferably full scale on the 20W range and 200W range. You do this because you want to adjust your AT200 so it is reasonably accurate at full scale. Then adjust your AT200 so it matches the reading on your reference meter. On that point I would leave the 1kW range alone on the AT200 as it's unlikely that you would have 1kW at your disposal.

It should be clear that you need a carrier rather than an SSB transmission to do this adjustment. These meters are average reading and trying to whistle up the meter during adjustment is a poor technique.

Regards

Lou

Dan,

Please make sure that when you get done with your further exam, that you state what board was not "fully connected," and what wires were shorted and where they came from or went to. It is possible that the prior owner has gotten some wire connections mixed up. Every bit of info helps.

There are several high resolution schematics out there for the 820(S).
I think Mike-w5rkl at: w5rkl "dot" com has it, n6wk "dot" com does, and Ken Kemski k4eaa "dot" com has them for sure. Remember also, BEFORE removing any wire/connector takes notes, draw a picture or take good clear color pictures!

Hi Mike and All,

I took apart my 820S to get at the VFO and N6WK pictures helped (http://www.n6wk.com/). I shot the DeOxit in the VFO and blew it out with canned air. I powered it up and it was still skipping ~3Khz. I noticed that RIT was very stable last week, so I cleaned out the VR2 pot on the AF-AVR board for adjusting RIT. I could not get it exactly zeroed, but the skipping frequency was gone! I am satisfied where it is now and happy I can hear people not jumping around all the time. :) It was hard trying to transmit / receive when it was bouncing around.

Thanks to all who sent comments to me!

First off don't get frustrated, you have already made a good decision getting the Kenwood hybrid, and not the Yaesu FT-101. My advice is not to spend to much sweat on it it sounds like it had problems before you picked it up. You are just starting out don't saddle your self with a turkey you want to get on the air. There are a bunch of examples of the TS-520's, 530's, 820's and 830"s for sale at very reasonable prices.. I consider the Kenwood TS-830S to be the best hybrid transceiver ever made. The going rate for a very clean fully functional TS-830S is somewhere around $500 dollars. The TS-830S has a fabulous receiver and has that great vacuum tube sound. I have been running TS-520's for a couple of decades and they have done the job.

Hi Dave,

First, the "SPAM" label doesn't appear to be originating from my email
client, Thunderbird.

I'm going to see if this response has "SPAM" in the subject line.

Dave,

I didn't see SPAM being inserted in the subject line. I looked for it as the message came back through Yahoo Mail to my Thunderbird email client software and it wasn't there. I then looked on the group server message listings and it wasn't there either. I don't know where it's coming from.

I'll do some additional test to see if I can recreate the problem.

The "SPAM" thing is from some server between the originator and the
Yahoo dot bomb servers that is running a badly-configured
"SPAM-Assassin" anti-SPAM system.

The thing reads the mail message, and destination, as well as several
other headers in the email you send, "decides" that the message meets
the criteria which have been defined in its system, and adds to the
subject line.

It isn't you, it isn't likely to be your internet service provider, but
it is very likely someone that your ISP either uses as a mail relay or
as a mail-vetting system.

Talk with your internet provider. If they deny they are using
"SPAM-Assassin" software, then just ignore it. That's about all you can do.

thyanks Wes. This does not happen with messages I respond to on Yahoo Heathkit or other Yahoo groups so it can't be anything connected to my ISP. I only see it on Yahoo Kenwood Group.

I'm not going to worry about it, I'll just delete the word SPAM from the address if I see it in a message I'm responding to.

I am not electronically inclined and have another radio that better meets my needs. My Kenwood TS820 is putting out about 80 watts. I have received compliments on how it sounded when I used it. I would prefer a local pick up but will ship it for actual costs if necessary. I would like $275.00 for the radio. I also have a Kenwood MC50 mic that I would sell for $50.00 and a Kenwood R2000 receiver that I would sell for $300.00. All would be local pickup or actual shipping charges added if you needed me to ship it to you. Let me know by email if interested. These items can be seen on my QRZ page. Thanks, Mark KM4AHP

I found myself in your situation a few years ago. If you have not worked on radios of this type before, fixing this can be a daunting task. The 820 is fairly complicated. But like anything else, a complicated system is a combination of many simpler circuits. I highly recommend getting a LARGE printout of the schematic. I have also nice printouts of the schematics for the different boards I can send you.

You will need an RF signal generator, a frequency counter, a good multimeter, a scope (really helps in some cases) and patience. Read the service manual. Learn the circuits and their inputs and outputs. Knowledge of the radio is your best tool.

start with the simple things:
A simple thing to check are the relays. Dirty contacts make the rig act goofy.
Check the switch contacts. Clean them if dirty or intermittent.
Check the filter capacitors for bulging relief points. If you have an ESR meter check the filter caps with that also.
Lots of connectors in this radio, make sure they are clean and not oxidized.

With that done then:

Check the power supply and the regulators. Make sure they are working.

Then verify the het oscillator.
Then check the VFO

Inject a signal into the antenna connector and start a trace through the system.

Take a close look at the RF attenuator switch mounted on the front panel. I have had that one fool me. Broken wires and burned resistors.

Pretty general stuff, If you have worked on other electronics, you've got the picture. Do not blindly replace components. That usually results in creating other issues, frustration and cost.

There are many very knowledgeable people on this site that are glad to help. But, post with detailed information on what you find as you troubleshoot.

Good luck.

49737. Kenwood R599A Receiver

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-23 15:23:25 UTC
From: Mike W5RKL
Topic: 49737 Message: 49737

I have a Kenwood R599A receiver that's excess to my needs. The receiver has the 160 thru 10 (no WARC bands), 11 meter and WWV band switch positions plus both 6 and 2 meter converters. Receiver has ALL filters, CW, SSB, AM and FM. Modes include CW, SSB (USB and LSB), AM, and FM. Receiver is all solid state. I am including my last 16 pin rear panel plug with hood and strain relief, it's the vary hard to find plug.

The one problem the receiver has is the VFO warbles when tapping on the cabinet (it's not a dirty variable capacitor shaft to frame flex connection issue). The warble problem was there when I bought the receiver. I was going to pull the VFO to fix the warble problem but never got around to it. All dial lamps work, CAL works, meter works, and the top cover hold down snaps are there and work. There are no modifications that I am aware. The cabinet paint is original and the inside is very clean. Bands 160 thru 10, no WARC bands, work as do ALL modes, including the squelch control which works in ALL modes. Tuning is very smooth. I used this R599A receiver with my Heathkit SB-400 transmitter and vintage Heathkit Marauder HX-10 transmitter, it worked very well. I have a few R599 and T599 manuals on my website, unfortunately I don't have the R599A manual. All knobs are original and are not broken or chipped.

www.w5rkl.com

You can access the list of R599/T599 manual on my website. Once the home page comes up, click on Manuals, Docs, and Mods link and when page comes up, go to Kenwood R599/T599 section.

I am asking $150 plus actual shipping cost (I don't pack the item, I let UPS or FedEx agent do the packing). If interested drop me an email at my call at yahoo dot com.

49742. Arduino based DG5 emulator

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-24 21:01:14 UTC
From: sleander@...
Topic: 49742 Message: 49742

I have been working on a DG5 emulator after being inspired by a series of posts on Toddfun.com (http://www.toddfun.com/2013/02/07/arduino-frequency-display-for-kenwood-ts-520s-hf-ham-radio-part-1/). I have been in touch with Todd about the project, he never finished it because he didn't have a TS-520.

I was looking for a computer interface to simplify logging when I am using my TS-520S, not a digital display. By following what Todd had done, I was able to build the circuit and write the code. Later, I added an LCD display so it could work standalone and truly emulate a DG5. I had some PCB's made, and am currently working on the second version with some corrections and new features.

You can see pics, video's, and the schematic here: http://www.kv6o.com http://www.kv6o.com

http://www.kv6o.com http://www.kv6o.com

View on www.kv6o.com http://www.kv6o.com
Preview by Yahoo

Just thought I'd throw it out there in case anyone is interested in building one!

I am also interested in a DDS based VFO using the Arduino, wondering what folks experiences have been. I have a AD8950 DDS board that I have been playing around with here, and I did see what Bart, KB8BAB has done, but that's waaaaay more than I am looking to do! I just want to emulate a VFO-520, a chassis with an Arduino, the DDS board, a rotary encoder, LCD display and maybe a couple of switches should be all that's needed.

OK, so this isn't truly a Kenwood specific question, but it is a Ham question:

Which is better for tensioning a long wire antenna? a screen-door spring? or a weight? Why?

If the answer is "a weight", what is the best way to "contain it" so that it doesn't swing around violently in the wind?

I always used springs in the past but that was many moons ago and maybe people have better ideas now.

It depends on how much tension you require.

I use a pulley with two plastic one gallon bottles of water. That is enough to keep the wire taut and horizontal. Even when the wind blows strongly the bottles move a little but not wildly - about a foot each way. I guess you could use a couple of slack ropes to restrain the weights from moving in certain directions if space around them is tight.

> Which is better for tensioning a long wire antenna? a screen-door spring? or a weight? Why?

A weight, because of the range of automatic adjustment. With a spring, if there is a lot of wind, you can easily reach either the modulus of stretch for the spring (and thus the spring goes "SPROING!" and breaks) or the modulus of elasticity of the wire ((and thus the wire goes "SPROING!" and breaks).

I've never seen the need to worry about the counterweight swinging too far. I guess it could be an issue, but since every time I've done this, I have made the default "no wind" (or very light winds) position of the counterweight, "ON THE GROUND" - even with our storms the problem never came up. And since wire sag doesn't make much difference in the signal (and can't be eliminated anyway, it would take infinite force to get a "perfectly straight" wire - in other words in this universe it isn't possible) an iron sash-weight or a concrete block (7 or 8 kg, ~15 pounds?) has been plenty of weight for the purpose.

Guys, there is a nifty antenna tensioner available from antennatensioner.com.

It's a mount it and forget it setup. I have seen one in action and it works exactly as it shows in the video.

Take a look and see what you think.

Gee....I guess it shows.... Industrial, started out in Mechanical back in the 70's, Electrical when I have to. Problem with EE for me is that I started out before High School learning that electric current ran the "wrong" way....

(High School is where I spent 4 years in the electronics shop down in the industrial ed wing, and 3 years (concurrently) in the metals shop, and summers since I could pull the bellows handles doing odd jobs for two old guys who had the last smithy in the area. Couple of semesters in the small engine repair shop, even more time down the hall mucking with an IBM 360-13, and blowing up the biology and chemistry labs. Fulminated mercury is just too derned easy to make. And a nightmare to get shot of once you realize that you actually HAVE made it.... There's a small crater in the sidewalk outside that window.)

Yeah. I'm one of -those-. I read entirely too much. Dangerous -and- crazy.

I WILL build something to make it to low earth orbit one of these days. It'll have a 2-meter beacon on board at the very least. The engine design should have plenty of thrust and to spare, using JP-4 and hydrogen peroxide, with a platinum ceramic catalyst (scavenged from a car's catalytic converter of course).

Confounded venturi throat and combustion chamber can't be made of anything I can machine at home, too bleeding hot. It just disintegrates and blows the <heck> up. Maybe graphite? Some kind of composite?

Oh well. Getting too old for this insanity, I might as well just admit it and give up.

I must admit, I'm a bit puzzled about all these questions about springs
and counterweights for wire antennas. Is this perhaps needed in areas
where you get winter ice buildup?
We don't get snow in Auckland and only very occasional winter frosts, so
all I've ever used is a halyard with a bit of natural spring to it. We
do get winds up to 150 km/hr sometimes and although I'm in a expos
ed site I've never had a failure.

I have one end of my OCF fixed to the corner of the house and the far end at the top of a palm tree (my only tall tree). It sways a lot in the wind and we have strong windy storms down here in south florida all summer. I have a pulley at the top of the palm with a lead diving weight hanging down to a few feet above ground. I don't let it go lower so the lawn guys don't go over it.

It works great and has survived two years so far with no issues and sometimes i see it going up and down 2 or 3 feet to compensate for the swaying. The line keeps the movement of the antenna wire to a minimum. The line and antenna wire are still going strong. Near the bottom i tied a loose loop around the tree and the drop line so it only goes up and down and not swing too far away from the tree.

I'm trying to use the 1410 with my ts-520s, every time I plug it in the rig keys. It works in my ts-440s no problem. I found this: Q4 and Q5 are the "Negative" keying transistors. More than likely Q5 is shorted internally which is causing the 520 to key up when the keyer is plugged into the CW socket.

If Q5 is found to be bad, the NTE-288 can be used as a replacement. Mouser sells the NTE-288 under part number 526-NTE288 for $1.05 each.

They seem to be good, the 520s works with a straight key.
Any Ideas?

thanks Eddie - kj4fgi

Eddie,

I couldnm't kind any specs on the keying requirement for the TS-520. So here is what I would do.

Connect a phone plug with wires to the KEY jack. One of the wires will be connected to the chassis and the will be "hot". Using a VTVM or DMM measure the voltage drop between the hot wire and ground. Note, I have read that it might be a negative voltage. This will be the open circuit voltage.

Next, connect an ammeter between the two wires. This WILL key the rig so do it on a dummy load. Quickly measure the current as you don't want to keep the rig keyed for more than a few seconds if operating at full power. You might even be able to do this test with the heaters off.

You now know how much voltage the keyer need to withstand and how much current it needs to sink. Compare that to the specs of the output transistors in the keyer.

Eddie,

Did you read the TS-520 manual, pages 15 and 16? The top left corner of page 16 shows the "REMOTE" 8 pin octal socket pin outs.

You did not provide the make and model of amplifier you will be using.

The TS-520S can be used with most amplifiers without an relay interface.

For best performance you should use the ALC connection.

The TS-520S 8 pin octal socket, pin 5, is the Normally Open relay connection with ground on pins 1 or 4. Pin 5 shorts the amplifier's center terminal on the amplifier's RELAY socket to ground (pins 1 or 4) when the 520 transmitter is keyed, activating the amplifier.

The TS-520S 8 pin octal socket, pin 6, is the ALC connection with ground on pins 1 or 4. The amplifier's ALC connection is made to pin 6 with ground on pins 1 or 4.

Most modern amplifiers use 12VDC 80 to 100ma switching relays. The TS-520S can easily handle that voltage and current ratings.

Use shielded cable to connect the amplifier to the ALC and relay connections on the TS-520S REMOTE octal socket.

Eddie, the 440 certainly did need the ALC as that is available and recommended operating practice. It is always good practice to keep your audio signal under control. Your SB-200 manual should be able to show you connections. As far as a relay interface, maybe not necessary, but certainly a good failsafe practice to provide a good dry contact EXTERNAL of the radio simply because you don't want to stress the relays on the radio boards. It seems from your comments that if you want to run an amp, you should be sure to read up on the practices of running one instead of onsey twosey answers. Personally I see no need for one. I chat around the world on 100 watts on a compromised vertical. You have a vintage radio and finding a cable all made up for you just may not be out there. Fire up that soldering iron and make one, that is what Ham radio is all about. Brad KB2CHY

Subject: Re: [TS-520_820_530_830] TS-520s and Heathkit SB-200

Eddie,

Did you read the TS-520 manual, pages 15 and 16? The top left corner of page 16 shows the "REMOTE" 8 pin octal socket pin outs.

You did not provide the make and model of amplifier you will be using.

The TS-520S can be used with most amplifiers without an relay interface.

For best performance you should use the ALC connection.

The TS-520S 8 pin octal socket, pin 5, is the Normally Open relay connection with ground on pins 1 or 4. Pin 5 shorts the amplifier's center terminal on the amplifier's RELAY socket to ground (pins 1 or 4) when the 520 transmitter is keyed, activating the amplifier.

The TS-520S 8 pin octal socket, pin 6, is the ALC connection with ground on pins 1 or 4. The amplifier's ALC connection is made to pin 6 with ground on pins 1 or 4.

Most modern amplifiers use 12VDC 80 to 100ma switching relays. The TS-520S can easily handle that voltage and current ratings.

Use shielded cable to connect the amplifier to the ALC and relay connections on the TS-520S REMOTE octal socket.

1. When you use an external HF amplifier with a commercial transceiver, you are essentially adding and additional stage of RF amplification AFTER the transceiver's internal Transmit/Receive (T/R) relay.

2. It is essential that these 2 devices operate in concert or synchronization or damage to one or both devices can occur.

3. Your Kenwood TS-520 is your operator interface, it MUST control the actions of both.
The TS-520 has the SWITCH contacts to operate the amplifier remotely (think of this as an ordinary light switch). these contacts have a voltage and current rating
The SB-200 has the (~ 110 V) voltage -- that when closed operates the amplifier.

The SB-200 was designed in the tube era when switching this voltage was not uncommon.
[I]However, with the appearance of solid-state design in the 1980s -- the radios became smaller. So, the voltage and current rating of many of the internal relays (or solid-state switches) dropped to lower voltage ratings.

4. I am an advocate of either installing the Soft Key modification inside the SB-200, so that it can work with ALL transceivers (tube and solid-state) OR an external keying interface (relay or transistor switch). Why address a problem multiple times?? -- just address or modify the SB-200 once to be all-purpose.

Copy and paste of some very good info. Note the voltage of the SB-200 keying circuit. Brad KB2CHY

Thanks Brad,
I do have a soft key relay that I used with my ts-440, I purchased the cable and relay assembly from k4avu, it was not interfaced to use an ALC. I used the carrier/mic. controls on the 440. I'll see about getting an 8 pin octal socket, if not I'll hard wire it into the 550s and I'll use the relay interface. Thanks, I guess I'll use the ALC on the 520s also.

Brad, thanks for taking the time replying, much appreciated.

The TS440 and newer rigs use a low positive voltage and the older tube and Hybrid rigs, like the TS520 use a higher negative voltage like tho older all tube grid block keying. If your keyer has solid state switching as an output it will not key the 520, you need to make an interface to reverse the keyed polarity , usually one transistor with a high enough breakdown voltage, will do it,.

Eddie,

You said your TS-440 didn't need the ALC connection. I don't know who told you and/or why you didn't need the ALC connection between your TS-440 but they were wrong. You should always use the ALC connection between your exciter (TS-520 or TS-440) and your linear amplifier! I recommend you download and read the pdf file on my website that discusses basic amplifier concepts:

www.w5rkl.com

When the home page comes up, click on Manuals, Docs, and Mods link at the top of the page. Once that page comes up scroll down to the bottom of the page and click on the Basic HF Amplifier Concept by VA7OJ pdf file, the file will download to your computer and should automatically come up in Adobe file reader.

If your amplifier is the SB-200 then the relay voltage is rather high, approximately -100VDC. If you have added the "soft key" circuit to your SB-200 then that high voltage is reduced down to a very low DC voltage.

The TS-520 also produces ALC during sideband transmissions. ALC is used to control the gain of the sideband transmitter to maintain linearity and to keep from over driving the amplifier. I read quite often where hams say, "I don't need the ALC connection, I keep the power output low." Well that's fine "IF" the person always pays attention but quite often most operators do not pay attention and end up over driving their amplifiers causing splatter and in some amplifiers, blowing the tubes or tripping the over drive circuit in the amplifier.

John K8JD,

You said

"If your keyer has solid state switching as an output it will not key the 520....."

That's not true I'm sorry to say.

The TS-520 CW keying voltage is -65VDC grid block keying voltage and the HD-1410 and any other solid state keyer that can handle that level of DC voltage will key the TS-520.

The Heathkit HD-1410 keyer is designed to key both positive AND negative keying voltages. The HD-1410 will even key a high voltage cathode keying circuit such as the Heathkit DX-40 which is what I use my HD1410 keyer for.

IF the HD-1410 keyer, when connected to the TS-520's CW socket on the rear panel, results in the 520 keyed constantly in CW mode then the negative keying transistor(s) is/are bad, most likely shorted internally. A quick fix, until the bad HD1410 negative keying transistor is replaced, is to "reverse" the wire connections at the 1/4" mono CW key plug that's plugged into the rear panel CW socket. The HD-1410 keyer should now key the 520 without any problem. Once the negative keying transistors are fixed, swap the 1/4" plug wires back and the HD-1410 keyer should key the 520's negative grid block keying just fine.

Dan: I repaired a 820 in the past.
With what you said, I would check the voltages on all the boards. You are correct to start there.
Check the antenna relay and make sure signal is getting thru it. Sometimes it needs a cleaning. Spares are available. I have even seen the antenna connector have a short that I could not see. This resulted in a very quiet radio that worked very well with the jack replaced. It did not test shorted with an ohmmeter, it was an RF short.
Since you are working on receive, don't worry about the transmit volts till you get ready to turn that part on, then measure volts before doing anything else. Could be bad bias caused holes in tubes. You can service radio without tubes but insulate the tube plate cap connection so you dont arc or zap yourself.
The counter board is crappy. Thru hole connections can be intermittent problems and very frustrating. Best solved by putting silver wire thru the thru hole connections and soldering on both sides. That can wait.
I use real silver plated jewelry wire bought at Hobby Lobby(always print a 20% coupon from their website), solders like a dream.

49786. Re: [TS-520_820_530_830] Heathkit HD-1410 and 520s

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-28 01:27:02 UTC
From: John Davidson
Topic: 49768 Message: 49786

t I Now that I rethink the old Hallicrafters "TO" keyer, it had a special fast acting relay so you could key anything with it. Just contacts closing, going to the output line.

My radio is Ham Radio...CW is Real Radio

John K8JD,

You said

"If your keyer has solid state switching as an output it will not key the 520....."

That's not true I'm sorry to say.

The TS-520 CW keying voltage is -65VDC grid block keying voltage and the HD-1410 and any other solid state keyer that can handle that level of DC voltage will key the TS-520.

The Heathkit HD-1410 keyer is designed to key both positive AND negative keying voltages. The HD-1410 will even key a high voltage cathode keying circuit such as the Heathkit DX-40 which is what I use my HD1410 keyer for.

IF the HD-1410 keyer, when connected to the TS-520's CW socket on the rear panel, results in the 520 keyed constantly in CW mode then the negative keying transistor(s) is/are bad, most likely shorted internally. A quick fix, until the bad HD1410 negative keying transistor is replaced, is to "reverse" the wire connections at the 1/4" mono CW key plug that's plugged into the rear panel CW socket. The HD-1410 keyer should now key the 520 without any problem. Once the negative keying transistors are fixed, swap the 1/4" plug wires back and the HD-1410 keyer should key the 520's negative grid block keying just fine.

From: W5RKL
Topic: 49768 Message: 49787

Hi John,

The Hallicrafters HA-1 TO keyer is the same as the Eico 717 vacuum tube keyer. Both keyer outputs use a fast acting "Reed Relay" that keys the the circuit. I own an Eico 717, it's a great keyer, but age can take it's toll on the components such as resistors and some caps plus the tubes that can cause sporadic errors now and then. These keyers are not iambic keyer BUT that doesn't mean the operator cannot connect a single paddle or Iambic paddle to either keyers. Either paddle you just don't have squeeze Iambic keying, only finger/thumb action which some refer to as "slap" keying, the thumb and fingers move the paddle(s) left and right to make the dits and dahs instead of squeezing the Iambic paddles to make the dits and dahs.

The HD-1410 will work with negative grid block CW keying which is what all Kenwood hybrids, Heathkit HW-100/101 and SB-100/101/102, the HX-1681 hybrid transmitter, the HX-20 SSB/CW xmitr, and the HX-10 Marauder xmtr. It will also work with many other vacuum tube and hybrid transceivers such as Swan, Collins, Drake, and many Cathode keying xmiters such as Knight T-60, T-150, Heathkit DX-20, DX-35, DX-40, DX-60, and others. The only problem I have with the HD-1410 keyer is the side tone adjustment, the tone range is limited.

The Heathkit HD-10 keyer will key any negative grid block CW transmitter that has a negative voltage less than -102VDC. This means it will work with the above listed transmitters/transceivers without any modification. The HD-10 will not work with cathode keying, the voltage is too high plus it cannot be used with a Swan 350 or 400 transceiver, the CW keying voltage is too high.

The MFJ-407B and MFJ-407D are also good all solid state keyers. I have both keyers and use the 407b with my Drake transmitters and the 407d with my Heathkit SB-100 and HW-101. I have used the 407D with a Kenwood TS-820 a few years back before I sold it, the 407d keyed the 820 just fine. I had to set the internal jumpers so the keyer worked with Grid block keying but other than that, it works great.

Date: 2014-09-30 17:55:56 UTC
From: john
Topic: 49789 Message: 49789

Hi

Would anyone be kind enough to supply me with the wire colours and corresponding pins for the mic socket on a TS-530s?

I think my mic socket has been re-wired to take another mic(non Kenwood)

Thanks

John

John,

Why do you think that the socket was rewired? Seems to me that it would be much easier to rewire the mic plug itself...but anyway..

Looking at the socket from the BACK SIDE:

Pin # 1 = White
Pin # 4 = Black....the above white and this black split off from a RED

Pin # 2 = White/Orange
Pin # 3 = small silver wire going to ground..more than likely to a lug on the "phones" jack right above.

Pins # 3 & # 4 have a very small .01 capacitor connected across them.

Connect all wires and grounds as shown or you'll get a rather nice hum in you signal.

Okay, re-reading – you want the color and pin numbers in the rig itself. Sorry, I don't have that at hand. If no one else has it, I'll try to dig it up.

From: srdente@...
Topic: 49793 Message: 49793

Hi everyone, This is the first problem I have had had with this rig since I got it about three years ago. I went to tune the drive on my 520s with the meter on ALC, tune mode, and SEND on, I get nothing on the meter, needle at 0. Set carrier control to max and still 0. I am not sure what I should check next. I am open to suggestions. Dennis

Please remember to include call sign(if any) per group policy when posting. 73 Joe wb7uqu

49794. Re: [TS-520_820_530_830] drive tuning

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-09-30 22:30:55 UTC
From: Joseph Stiles
Topic: 49793 Message: 49794

Dennis,

Is the rig receiving? If not check the 9 pin shorting plug on the rear for proper contact. Without this plug or other shorting method between pins 8 & 9 rig will not operate tx/rx.

SG switch on rear of rig on?

Are you getting any RF output when rig is not in "tune?"
Will it tune up in "CW?"

Is this problem on all bands?

It is possible that your driver tube, the 12BY7A has failed. They usually
go slowly...but ya never know

It is also quite possible that resistors 5 & 6...both 56k on the HV unit have failed or most likely gone very high in value. The two resistors decrease voltage to the final amplifier tubes during "tune mode" so as not to hit them with full voltage while being out of tune/resonance.
Lack of "ALC in Tune" is a very common problem that has plagued just about every KW hybrid at on time or another.

You can check the voltages by testing at the "TUN" or "210" post on the HV board...should be around 210VDC or so.

BE CAREFUL AS YOU WILL BE VERY CLOSE TO 800VDC...WHICH WILL MAKE YOU SK.

If you are not comfortable find someone who is. No sense ruining your day. Even a couple hundred will give you a real decent jolt..it can also make you and SK.

I suggest that you obtain, if not already, a good clean & clear service manual. Several sources: n6wk "dot " com , w5rkl "dot" com. There are a couple of others, but these just came to mind.

What testing equipment and skill/knowledge level do you have?

49795. TS-530 800 hz. shift

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-01 10:54:10 UTC
From: mgbv8@...
Topic: 49795 Message: 49795

Hi everyone. Found another problem with the 530 I bought a couple months ago. Decided to try it on CW and when I go to CW it does not shift up 800 hz. If I try to listen to ARRL at 7.0475 I have to tune to 7.0467. But when I go to tune it shifts up but I still have to tune back to 7.0467 to receive the signal. Just using this frequency as an example. It does this on all bands. Thought someone might have seen this before. Thank Bill WR4G

49800. Wrong information

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-03 00:59:51 UTC
From: wagstw46@...
Topic: 49800 Message: 49800

TS-820 Owners:

I am trying to help a fellow off line with his TS-820S issues. He did a search under the Conversations Search Groups to see what the signal levels at the DG-1 Counter Mixer board should be. He found one of my old responses that describes the two necessary rf inputs. CCR is Carrier signal from the IF board and CVC is VCO signal from the PLL PD board.

In my response I stated that CVC is VCO level at approx 900mv rms. That is wrong.

The correct answer is it is VCO signal at approx 100mv rms level.

The question then was how does the 900mv VCO signal become a 100mv signal at the Counter Mixer board Molex connector. The VCO signal from the PD board is supplied to the Counter Mixer board thru a resistive voltage divider on the PD board using a 470 ohm and 150 ohm resistor. At the center tap of this divider the 900mv signal would be divided approx to 300 mv level. However, that signal is applied to the Counter Mixer board to the base of buffer amp Q4. In the path to the base of Q4 there is a 100 ohm shunt resistor. That resistor is effectively in parallel with the 150 ohm resistor on the PD board so the divider is a 7.8 to 1 divider and not a 3.1 to 1 divider. So the CVC level at the Counter Mixer board then becomes 900mv/7.83 = 114.9 mv or approx 115mv. Anything around 100mv is good.

Correct response should have been:
1. You adjust the CCR (carrier level) by first adjusting CA2 at Carrier Osc unit for 300mv at TP-5 on the IF board and then adjusting TC-1 trimmer cap on the IF board for a 100mv signal at TP-6 (see step 3-2-2).

2. If the VCO is functioning correctly you should have approximately 100mv at CVC on the Counter Mixer board. No adjustment normally required.

Sorry for the bum dope!

Terry K9TW

Nathan,

Before you invest time, money, and components repairing the 2 boards you have, turn the AF AVR board that's in your 820, over, foil side facing you, and note the foil side number you see. It's not enough just to have the AF AVR board's component side number be the same, the foil side number must also be the same otherwise you could end up with a rebuilt board that will not work in your 820. I've been down this road before.

Mike, Good call on checking the numbers. Of the 3 I have(1 in the radio, 2 spares), one of the spares matches, the other does not. Glad I didn't rebuild the wrong one!

Joe,
Yes, VR1/VR2. This radio is long past the point of "restoration" or historical accuracy, so I am toying with the idea of using a piece of perfboard and pigtailing a few modern trimmers, because I'm not finding anything that looks like it will fit in that location.

Dennis,

No, +260VDC is NOT too high at the Rectifier Unit's 210A terminal. The 210A +260VDC is the "No load standby/receive" voltage level you would expect to see at the RF Unit's 210A and Final Unit "SG" terminals with the 520 in standby/receive.

When the 520 is placed in transmit, current will flow in the driver tube and both final tubes. This results in a voltage drop to occur in the tube's screen circuit causing a "voltage drop" to occur in the tube's screen circuit. If you measure the tube's screen voltage you will notice it has "decreased" some what. As the current flow in the screen circuit varies, so does the voltage drop. Higher screen current results in a higher voltage drop to occur. The reverse applies, lower screen current result in a lower voltage drop in the tube's screen circuit.

This is how vacuum tubes work and if this sound strange to you then I recommend you spend time studying vacuum tube theory in the ARRL handbook, mid 60s and earlier edition are best.

From: W5RKL
Topic: 49793 Message: 49810

Dennis,

If you do not see any ALC in TUNE mode but you see 60ma idling current, try tuning the 520 up in CW mode. If you can tune the 520 up in CW mode but not in TUNE mode then R5 and/or R6, both 56K 1/2W resistors on the HV Unit board are out of tolerance. If you find either resistor out of tolerance, replace both resistors with new metal film 56K 1/2 watt resistors.

Here's what happens when the MODE switch is set to TUNE and the transmitter keyed.

R5 and R6 form a resistive voltage divider. The Rectifier Unit's 210A voltage, we'll say it's +260VDC, is applied to the "210A" terminal of the HV Unit board. The current flowing through R5 and R6 with +260VDC applied to the 210A terminal is approximately 2.32ma

I = E / R

260 / 112000 = .00232

This results in a voltage drop across R6 of approximately 129.93VDC

E = I x R

.00232 x 56000 = 129.92

The +129.92VDC voltage drop across R6 results in a positive DC voltage at the junction of R5 and R6 and at the HV Unit's "TUNE" terminal of approximately +130.07VDC

260 - 129.92 = 130.08)

which is the screen voltage applied to the 6146 screens (260 - 129.92 = 130.08) in TUNE mode.

This reduction in screen voltage causes a reduction in current flow in the 6146s in TUNE mode, hence the reduction in DC power input in the final amplifier in TUNE mode. Switching the MODE switch to USB, LSB, or CW, returns the normal +260VDC to the final tube screens.

Also, Dennis, you need to add the required message signature to ALL of your messages you post on this group. Please pay attention to your messages and add the message signature. 49812. Kenwood Hybrid Net updated (October 5, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-05 19:14:23 UTC
From: Mark Gilger
Topic: 49812 Message: 49812

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There
were 18 stations checking in under good band
conditions. There were 2 new first time check-ins: KV4ZA, AA3OI.

We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
5 running TS-830S
0 running TS-511
0 running 599 twins

The Sunday net was run by me, WB0IQK. There were
17 stations checking in under fair band
conditions. We had the following number of radios
checking in. There were 4 new first time
check-ins: KC7RUN, W5TMP, KG6IRG, and N7XGH

1 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
4 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-940S & Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

49813. S-Meter deflects Maximum with No audio output when WWV is selected: TS 520s

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-05 19:54:34 UTC
From: Henry Stephan
Topic: 49813 Message: 49813

Hello Mike and the Group

Firstly Mike W5RKL, I echo Scott's sentiments and would like to complement you and thank you for your valuable input. I had a problem when selecting tune and no output was indicated on the meter and found, as you rightly pointed out, that R5 was open circuit & R6 was out of tolerance on the HV board. I replaced both with carbon resistors as well as R7 (12k) of same characteristics, but I notice you recommend metal film. Any reason for recommending metal film and not carbon resistors? This question is out of interest on my part.

Secondly, I have a puzzling problem where, when I select WWV on the Band Switch, the s-meter deflects to maximum. It is almost as if the RF Gain has been turned fully counter clockwise. At the same time the audio is fully muted, once again as if the RF Gain Control has been turned fully counter clockwise. Also when I switch the TS 520s off and switch it back on again, with the band switch in the WWV position, audio is present for a moment until the s-meter reaches a certain point on the scale and then audio is muted once more. This only occurs when WWV is selected, all other bands behave normally when selected.

Has anyone possibly experienced this phenomenon and what was the fix for the problem?

Many thanks for your replies and assistance.

Best 73

Henry de ZS6MC

49814. Re: [TS-520_820_530_830] TS-530 800 hz. shift

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-05 21:20:46 UTC
From: Joseph Stiles
Topic: 49795 Message: 49814

Bill,

I am very confused by your description of the problem. I have read it about 10 times and do not fully understand what you have going on.

With your rig in "CW" mode, it should shift up 800Hz ONLY when the transmitter portion of your rig is keyed, UNLESS the "800 up" adjustment on the VFO has been messed with.

Putting the "MODE" switch in "TUNE" automatically shifts the VFO UP 800Hz without keying the rig. When you key the rig and the mode switch is in tune...you will NOT get a further 800hz shift up. The tune mode is designed to allow you to tune up your final amplifier section under reduced voltage. When using rig in CW mode you can just tune in the other station's CW tone at appox. 800hz tone in your speaker/headphones...so when you transmit...your signal will be rather close to the other station receive freq. Also, you can use your 800Hz CW side tone to get right on freq. With out using the send/receive switch or VOX, use your key to put transmitter in send...your should hear the 800Hz side tone from your rig...move the VFO knob up or down until the CW tone on your rig matches the others rigs CW tone.

If you have a frequency counter and a service manual, may I suggest that you look at Pg 34, steps 3, 5, & 6.

Henry,

I use a variety of modern resistors, Metal Film just happens to be one type I use.

Modern resistor come a variety of "types" such as /*Metal Film, Carbon Film, */and /*Metal Oxide*/.

I do not use old Carbon resistors and yes they are still available.

When using resistors one must take the time and read the resistor type data sheet (Metal film, Carbon film, or Metal oxide). The data sheet will provide information including the voltage rating of the "type" of resistor.

See the following resistor data sheets for information pertaining to the type of resistor and it's specifications.

The following link is f*o*/*r Koaspeer */*metal film *resistors*:**

I forgot to comment about the power dissipation in the HV Unit's R5 and R6 resistors.

The tech must consider the power rating of the resistor to be used. For example, if a resistor was replaced by a previous owner and they didn't consider the power rating of the resistors and it failed for YOU, you could easily replace it with the same "wrong" power rating. What is the power rating of a resistor? It's the maximum "safe" power dissipation in "Watts" the resistor can handle. The formula for determining the power rating of a resistor is

P = Isqrd x R

The tech MUST know the maximum current that will flow through the resistor in order to properly select the correct power rating of the replacement resistor.

Let's take the 56K resistors, R5 and R6. We use +260VDC at the DC voltage applied to the HV Unit's "210A" terminal. The +260VDC is applied to the series string R5 and R6 to ground. We calculated the approximately current flowing through the resistor series string as being approximately 2.32ma (260 / 112000 = .00232).

We then calculated the voltage drop across R6 which was approximately 129.92VDC. Okay with 129.92VDC dropping across R6, what is the power consumed in R6? We use the above forumla,

P = Isqrd x R

where "Isqrd" is the "square key" on your calculator OR by simply entering the following

.0232 x = x 56000 .301 watts

which is the same as entering the following on your calculator:

.0232 <press calculator's sqr key> x 56000 = .301 watts

either method you get the same answer.

The total power consumed in R6 is slightly over 1/4 watt so a 1/2 watt resistor would be fine. You could increase the wattage of R5 and R6 to 1 watt but the amount of time the 520 is in TUNE mode transmit doesn't support increasing the resistor power rating to 1 watt so 1/2 watt will do fine.

Okay, what about R5? What power rating should it have? Okay, do the same thing except use the voltage value of "130.08VDC" NOT "260VDC". Why not 260VDC? Because a "voltage drop" occurs across R6 resulting in a DC voltage at the junction of R5 and R6 of "130.8VDC" NOT "260VDC" AND the same current, 2.32ma, flows through R5 as it did through R6!! This is important to know. I've been questioned about the current level being different in series resistors, which is NOT true!! The same 2.32ma flows through R5 and I will prove it in the following simple Ohms Law math calculation:

If the DC voltage applied to R5, at the junction of R5 and R6, is 130.8VDC and the Ohms Law formula for current is

I = E / R

then

130.08 / 56000 = .00232

the exact same current that's flowing through "R6" AND the same "power rating" of R6, .301 watts. Even if R5 had a different resistance value than R6, the same current would flow through the "different" resistance value as it would through R6, in a series circuit. I have a video on my website where I show how this works with 3 resistors, all having different resistance values, different voltage drops, but all have the same current flowing through them. Click on my website's "Videos" link at the top then click on the Introduction to Basic Ohms Law "Series Resistor Theory" video link. These are simple basic electronic subjects that all hams who are servicing their ham gear SHOULD KNOW!

From: lonelyone_64109@...
Topic: 49817 Message: 49817

I am looking for a source of paddle switches for my TS-520S. The VOX paddle switch has become stuck in the up position and I would like to replace it. I have looked at several sources including Mouser with no luck. If anyone can help me with this I sure would appreciate it.

If there is a "fix" on how to free up the switch by using DeOxit or whatever I'd like to know as well.

Paul WB0CJB

Subject: Re: [TS-520_820_530_830] TS-530 800 hz. shift

Bill,

I am very confused by your description of the problem. I have read it about 10 times and do not fully understand what you have going on.

With your rig in "CW" mode, it should shift up 800Hz ONLY when the transmitter portion of your rig is keyed, UNLESS the "800 up" adjustment on the VFO has been messed with.

Putting the "MODE" switch in "TUNE" automatically shifts the VFO UP 800Hz without keying the rig. When you key the rig and the mode switch is in tune...you will NOT get a further 800hz shift up. The tune mode is designed to allow you to tune up your final amplifier section under reduced voltage. When using rig in CW mode you can just tune in the other station's CW tone at appox. 800hz tone in your speaker/headphones...so when you transmit...your signal will be rather close to the other station receive freq. Also, you can use your 800Hz CW side tone to get right on freq. With out using the send/receive switch or VOX, use your key to put transmitter in send...your should hear the 800Hz side tone from your rig...move the VFO knob up or down until the CW tone on your rig matches the others rigs CW tone.

If you have a frequency counter and a service manual, may I suggest that you look at Pg 34, steps 3, 5, & 6.

Bill,

I think you're not seeing the 800hz shift. I mean on disrespect but the answer is right in front of you.

You say you receive on 7046.7Khz but when in transmit the displays shows 7047.5Khz. If you do the simple math you will see the VFO does shift 800hz when in transmit!

7047.5 - 7046.7 = .800

or 800Hz.

When switching back to receive, the frequency shift down 800Hz, back to 7046.7Khz. That's what it's suppose to do!!

Sounds like you need to run through the receiver alignment procedure in the service manual (or the owner's manual - I think it's in both but I just use the one in the service manual).

Part of the procedure in there is to get the receive and transmit oscillators exactly synched to be on the same frequency (within the limits of error of your measuring equipment, which is pretty derned close these days even with a run-of-the-mill freq. counter).

Joe, Moderators, Members et alii:

Would a document of some sort, sorted by callsign perhaps, listing the rig(s) we each have be of any continuing value to the group? It would obviate such postings as this one, for one thing. (The model he owns could be easily checked given the existence of this list, though there could still be confusion caused by those who own more than one model hybrid Kenwood.)

Just a stray thought. Won't hurt my feelings if y'all think it might be a dumb idea, or otherwise not workable.

49829. Mic Wiring Diagram for MC-50 to TS530S

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-07 15:29:18 UTC
From: n4mbi.rbb@...
Topic: 49829 Message: 49829

Question for the group regarding Mic wiring for TS530S to an MC-50 mic. I have a TS530S that was being used with a PC1A Phone Patch. The MC-50 currently has an 8 pin mic plug wired as follows: Pin #1 (Black), Pin#2 (Violet), Pin#7 (Shield), and Pin#8 (Red). Pins 3,4,5, and 6 N/C.

According to an old sheet that was with the PC-1A, to change this to a 4 pin mic plug, it should be wired as follows: Pin#1 (Yellow), Pin#2 (Violet), Pin #3 (Red), and Pin#4 (Shield).

Problem is, there is no yellow wire in the MC-50 cord, so would the Black wire still go to Pin#1? This seems a bit confusing.
I would appreciate a correct wiring diagram using the current Black, Violet, Red, and Shield to a 4 Pin plug to plug directly into the TS530S. I suppose I could just keep the PC-1A in line and just use it as an adapter, but really no longer use it.

Thanks in advance for the help.
Rick, N4MBI

49830. Re: [TS-520_820_530_830] Mic Wiring Diagram for MC-50 to TS530S

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-07 16:33:11 UTC
From: Ken Winterling
Topic: 49829 Message: 49830

Rick,

I am at work so my documentation isn't handy and I can't comment on the wiring color code. Regardless of the wire colors, I suspect that if the MC-50 with the 8 pin connector is working properly with the PC-1A while connected to the TS-530 the mic should work OK when plugged directly into the TS-530 PROVIDING that all of the wiring connections are as specified by Kenwood in the PC-1A and the mic. Did you try plugging the MC-50 directly into the TS-530? If so, what happened?

It is possible that the mic cable is not original and has different colors from the original or has been modified. Sometimes a wire(s) is clipped off close to the jacket and may even slip out of site. Look closely, there might be a yellow wire in the cable. Did you remove the cover of the connector at the other end of the cable to see what colors are present there?

Let us know what you find.

Ken

Ken,

You can find the wiring diagram in the operators/instruction manual. It doesn't matter what the color of wire..just how it's connected. Do not combine any ground connections...follow the diagram.

The 4 pin plug that goes to the rig is as follows:
Pin 1 = yellow
Pin 2 = violet
Pin 3 = red
Pin 4 = shield.

The above was taken directly from the MC-50 instruction sheet

Regardless of the wire colors, I suspect that if the MC-50 with the 8 pin connector is working properly with the PC-1A while connected to the TS-530 the mic should work OK when plugged directly into the TS-530 PROVIDING that all of the wiring connections are as specified by Kenwood in the PC-1A and the mic. Did you try plugging the MC-50 directly into the TS-530? If so, what happened?

Ken, sri abt that.

My MC-50 wiring instructions should have been to:

Rick-n4mbi

I also have up loaded the complete wiring diagram for the MC-50.

You all should have received the link to where it is in the "files" area
of the groups home page

WOW! CQP wiped me out more than I thought! Sorry about that.

It's for a Kenwood TS-520. Just the plain 520.

I THINK I found what I'm looking for but confirmation would be great.

On the 9 pin connector on the back (the one with the plastic jumper if you don't use the external VFO) pins 3 & 4 are ground & 12v. (respectively). Is this correct?

Chad,

Yes, pin 3 is ground and pin 4 is 12VAC on the REMOTE VFO socket. The 12VAC is use to power the dial lamps in the remtoe VFO plus the meter and dial lamps in the TS-520.

My station has been up graded. The TS 520SE now has the AT 230 and SP 520, now I only need a VFO 520 to make it complete, a DG5 is being repaired to be added soon. Joining it on the bench is a TS 520S that I picked up with a MC 50 and some other spares VERY CHEAP($350 aus). The 520S came with the SP 520 and the DG 5 that I put with the 520SE. I've posted some pics of my Babies hope you like them.

Topic: 49840 Message: 49840

Following on from the issues I have with the possible suspect mic wiring, I took the radio to the club last night and had one of the members have a look at it. We discovered that there is 70-80w of output from the set. But the other issue is, that if the band selector is set to say 14mhz and we adjust the plate control to 14mhz we have no dips on the needle. How ever do if the plate is tuned to 7mhz.
Also appears to be very little dip movement on some bands (also little output as well)and the band selector has lost its click as you select bands.

It is tempting to send the radio to someone to get repaired/checked out but I dont think the radio is worth spending out on. I paid £40 for it and I guess at around £100 - £150 *might* get it fixed.

Any thoughts on the issues above?

John,
I do not want to sound alarmist...but STOP! Your band switch coupler may have broken and any further attempt to tune it up..may and will cause more damage that is not worth it to fix.
1. Unplug rig from the mains2. let rig sit for a bit..to make sure the HV caps are totally discharged...DO NOT SKIP THIS STEP!2.a. remove top and bottom cover and the cover over the final amp cage
3. Test for voltage at the top of the plate choke or at the 800 terminal on the rectifier board.4. If not voltage...remove the front final amp tube.5. With a BRIGHT, light look at the white nylon bandswitch coupler as you rotate the bandswitch control6. There should be no slop..it should be crisp with positive stops. The detents are part of S-22, the tank tap selector switch7. If there is/are cracks..it will have to be replaced..no glue will work for any amount of time due to it being nylon and has a good amount of torque applied to it.8. If you have a 1.5mm "allen type" wrench you can loosen the set screws on the final amp end and slowly pull theshaft toward the front.9. The switch in the final amp cage can be rotated with a pair of needle-nosed pliers. Rotate the shaft until the flat parts of the short shaft are at 3 o'clock and at 6 o'clock, as viewed from the front.
10. Rotate the bandswitch knob and shaft so the band switch knob points to "10" not "10 meters"11. This is the correct orientation for the bandswitch...and is VERY IMPORTANT!
  Also, it is important that all of the bandswitch wafers are properly oriented too. Look at the white movingpart of the wafer(s), some are hard to see, but all have a small indented circle on them..with the knob pointing at "10", the flat parts of the shaft on the left and right (6 & 9 o'clock) the small circles should all be pointing to the LEFT or 9 o'clock. This is the proper orentation

Hello Ken,

Thanks for the advice on the mic situation. Due to the difference in the pin configuration I couldn't try the mic directly into the rig. As I bought this rig used back in 1984, I am not entirely sure what happened to it before I came along, however, I do think it was the original cord and the plug was most likely replaced by the original owner when he was setting it up for a phone patch. I did take a VOM today and checked out the pin assignments. While replacing the 8 pin plug with a 4 pin plug, I discovered that the "Black" wire in question was really "Yellow" under a black coating. This was was seen when re-stripping the wires to solder to a new plug. Why this yellow wire had a black insulation on it, I have no idea! At any rate this solved the mystery of the apparent "no yellow wire" and all works fine now.

Thanks again for your help on this.

One last thing. Is the plastic plug glued together? I tried to take it apart but I don't want to break it. I can't afford $10 for a new one.

Thanks

Chad,

I could be wrong but I believe the plug screws together.

The plug in question is two parts. You can try soaking it in a bit of soapy warm water for about 5-10 minutes. Using a small screwdriver, put it through the pins from one side to the other...and with the other hand, unscrew the cap section.

Hello everybody, new member here Alex B. kd8sdp. I have a ts 530s kw. It has a vfo that is drifting. So far I check it when it is cold and after it is been turned on for a long time. No difference. Can anybody give me some ideas to how to fix this problem. It is a real good working and a pleasure to work this radio. thanks for all help and ideas Alex B kd8sdp

Alex,

Can you define your VFO drift a little better? Does it drift continiually, just at initial warm up and by how much is it drfting/symptoms?

Thanks Mike. I checked the voltage between the two 56k resistors and had 130vdc.

Still no ALC when tuning. Transmits in usb and lsb OK. don't have a key to check CW.

Dennis,

You do not need a CW key to check or tune the radio up in CW mode! The rear panel CW key socket is a N.C. (Normally Closed) socket. This means with nothing inserted into the rear panel CW key socket, you can tune the transmitter up in CW mode WITHOUT a CW key!!

49857. Hybrid Net Update (October 12, 2014)

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-12 20:16:12 UTC
From: Mark Gilger
Topic: 49857 Message: 49857

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2012. The yearly check-in totals are posted at
the bottom of this message. It showed we had a
10% increase in our Saturday check-ins and an 8%
on Sunday as compared to the 2012 check-ins.

The Saturday's net was run by me, WB0IQK. There
were 15 stations checking in under good band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
4 running TS-530(x)
5 running TS-820(x)
3 running TS-830S
0 running TS-511
0 running 599 twins

The Sunday net was run by me, WB0IQK. There were
14 stations checking in under fair band
conditions. We had the following number of radios
checking in. There were 2 new first time check-ins: KC5PXI and W6TPR

3 running TS-520(x)
3 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

I was running my TS-820S & Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103
January 2014, Saturday☐s net total = 71, Sunday☐s total = 82
February 2014, Saturday☐s net total = 80, Sunday☐s total = 85
March 2014, Saturday☐s net total = 82, Sunday☐s total = 73
April 2014, Saturday☐s net total = 64, Sunday☐s total =43
May 2014, Saturday☐s net total = 66, Sunday☐s total = 35
June 2014, Saturday☐s net total = 43, Sunday☐s total = 59
July 2014, Saturday☐s net total = 24, Sunday☐s total = 46
August 2014, Saturday☐s net total = 62, Sunday☐s total = 53
September 2014, Saturday's net total = 49, Sunday's total = 27
October 2014, Saturday's net total = 33, Sunday's total = 31 (Month to date)

Just a suggestion:

The web page about the net says:

Saturday - 7.235 MHz @ 3:30 EST

In the interest of accuracy and avoiding confusion to newcomers, could
this be changed to say:

Saturday - 7.235 MHz @ 3:30 EST/EDT

49862. Question on HV Cap Replacement TS-520S

Yahoo group: TS-520_820_530_830 (2014)
Date: 2014-10-13 19:35:20 UTC
From: Donald Allen
Topic: 49793 Message: 49862

I'm installing two Nichicon 150uf 500VDC HV electrolytics that I purchased from Ken K4EAA for my TS-520S. The TS-830S HV electrolytics installation was a relative breeze, not so much with the TS-520S!

Stupid question... How do you access the rear sheet metal screw for the left-most electrolytic's mounting clamp (viewed from the top) which sits somewhat below the IF board sub-chassis area and directly in front of the power transformer? A small diameter, but long, Phillips screwdriver? I removed the Fixed Channel/AVR board and its mounting bracket, of course, but this specific screw is still inaccessible. I'm sure there has to be a way to access this screw, but I wanted to ask the group first before I dig into it further.

Tnx.

Topic: 49793 Message: 49863

Nevermind... I got it out using a 10" #1 Phillips that I had in my garage workshop. The clearance between the IF board sub-chassis, the power transformer, and the rear mounting clamp sheet metal screw on my unit is very tight.

I had forgotten how much more "fun" the 520S to work on compared to the 830S. Hi...

DON YOU HAVE TO HOLD YOUR MOUTH JUST RIGHT HI HI . THEY ARE A PAIN YES. A THIN SCREW DRIVER WILL HELP YES YOU MAY WANT TO TAKE ONE AND SET IT ASIDE JUST FOR THIS PURPOSE AND PUT A SLIGHT BEND TO IT IN A VISE THAT WOULD HELP YOU GET IT STARTED AND LOOSE SO YOU CAN WORK IT THE REST OF THE WAY OUT. HOPE THIS HELPS. JIMMY WB2KNR

Now I have another problem. Pin 3 is ground. Pin 4 also has continuity to ground when off and no voltage when on. I know it's on the meter light and heater circuit and they work just fine. It also connects to pin 7 on the molex connector.

1st, is it showing ground continuity because of the lights?

2nd, since I can't get to either the lights nor the heater switch very easily, is there another 12v source I can use?

Maybe I'll just find a plug in supply for the tuner meter. :-P

I mean no disrespect Chad but this is where studying the schematic will provide you with the answers to your questions.

Pin 4 will always show continuity to ground through the dial/meter lamps as well as the driver and both final tube filaments. The tubes and dial lamp cold resistance should be more than zero ohms.

You can tap off of the Power Transformer's "12.6" terminal. That terminal has 12.6VAC, same AC source voltage that is applied to and appears on the 9 pin Remote VFO socket pin 4. You can easily see this by following the schematic wiring from the Remote VFO socket pin 4.

Pin 4 goes to the main power connector on the rear panel, pin 7. A jumper wire goes from pin 7 to pin 10 in the socket that's plugged into the rear of the 520.. Pin 10 is then wired directly to 12.6 terminal on the power transformer secondary.

You will need a ground return connection for the 12.6VAC.

Sir,I recently joined the group and just completed restoring a TS-820S rig to full function with a lot of help from Terry (K9TW) and on-line resources, including this group. I'd like to post the following, but it's rather lengthy. Your opinion: is it worth posting and, if so, what's the best way? Just post as a email or put it in as a file and send a posting referring to it? Terry told me that these items might be of interest to the group, particularly the DG-1 fix.
Many thanks!DaveKC3CIP
